## SOQ USER GUIDE UPDATES

June 1980 Updates to SOQ80128

### INTRODUCTION

This document defines the changes made to the SOQ code (SOQ80128) between January and June of 1980. The changes either correct shortcomings found in the code or, more usually, document the increased capability being continually built into the code. The SOQ code is maintained as SOQ80128 June PL, ID = AFLOJRA as a NOS/BE-1 CDC update format file.

### UPDATES

#### 1. \*ID FIXZRN

This update redefines the coefficients to be input to the Zernike subroutine. This new convention is more physically meaningful in that, at least for lower orders, the coefficients are in waves. For example, to impose one wave peak to peak of defocus ( $P_4$ ) on a beam, one would input  $P(4)=1$ . The phase applied is now:

$$\phi(I,J) = \sum_k P_k \pi Z_k(I,J)$$

The subroutine affected is ZERN. This update does not effect the rest of the code.

#### 2. \*ID FIXJTR

This update ensures a correct definition of DF in subroutine JITRBG since when JITRBG is called from subroutine QUAL, the X-coordinate array contains  $R\lambda/D$  coordinates, not the spatial coordinates.

Only one line of the code is affected by this update.

#### 3. \*ID ROTZRN

Due to different coordinate system orientations for data, it became necessary to allow for this variation within subroutine ZERN.

Define the data x and y coordinates to be XROT and YROT, and the SOQ x and y coordinates to be XIN and YIN. The rotation angle is then defined to be  $\theta$  (in radians).

June 1980 Updates to SOQ80128

Page 2

$\text{COSROT} = \cos(\theta)$

$\text{SINROT} = \sin(\theta)$

$\text{XROT} = \text{XIN} \times \text{COSROT} + \text{YIN} \times \text{SINROT}$

$\text{YROT} = -\text{XIN} \times \text{SINROT} + \text{YIN} \times \text{COSROT}$

Application of Zernike polynomials to and SOQ point located at (XIN, YIN) would then be calculated using Z(XROT, YROT). The possibility of axis flips are also accounted for and are flagged by FLIPX or FLIPY not equal to zero. Namelist ZERNS is modified to include FLIPX, FLIPY and the rotation angle (in degrees) ZTHETA. No common was modified. This update modified only subroutines GDL and ZERN.

20. ABSTRACT (Continue on reverse side if necessary and identify by block number) This report describes the System Optical Quality (SOQ) code structure and the input to the code required for analyzing High Power Laser Optical Systems. The SOQ code provides the designer with a physical optics model of the system. The code traces the beam from its point of origin in the resonator through the optical train into the far field. This report is divided into three parts. Part 1 describes the general structure of the SOQ code and establishes a correlation between the usual optical elements encountered in the optical

train/gas dynamic laser resonator and the appropriate SOQ models. Part 2 acquaints the user with the individual SOQ subroutines and their analytical formulations as manifested in Fortran within the SOQ framework. It also delineates the input required to exercise the subroutines, familiarizes the user with the operation of the SOQ model, and contains working input modules which carry the user through the usual calculations of the SOQ code from input generation to loaded cavity calculations. Part 3 contains Appendices describing SOQ updates.

SECTION III  
MAIN EXECUTIVE CODE

1. PROGRAM SOQ

a. Purpose -- Program SOQ is the main driver program or executive code for the total SOQ code. Many parameters such as mesh size, number of points, initial position of the optical axis, the initial coordinate array, and the initial field itself are established in this routine. Once the above parameters have been initialized, there are several options available for operations on the field. Those available are:

- (1) Calling subroutine GDL, the executive program for propagating the field through the optical elements
- (2) Performing a quality calculation
- (3) Gradient search optimization
- (4) Parametric studies.

The above options can be activated in any order and as many times as desired by successive reads of namelist START. The flag for ending execution of the entire deck is to set WWL = 0 in the last read of START.

b. Formalism -- The only major explicit calculations done in SOQ are those which determine the initial field when it is not to be read in. The OPTIONS are:

- (1) Plane wave - constant amplitude
- (2) Plane wave - Gaussian amplitude
- (3) Spherical wave - constant amplitude
- (4) Spherical wave - Gaussian amplitude.

Letting  $E(x,y)$  represent the field,  $A(x,y)$  the field amplitude, and  $\phi(x,y)$  the field phase, then the field is determined by:

$$E(x,y) = A(x,y) e^{i\phi(x,y)} \quad (8)$$

where

$$A(x,y) = \frac{\text{const.}}{\text{const.}} e^{-\left(\frac{x^2}{\sigma^2} + \frac{y^2}{\sigma^2}\right)} \quad (9)$$

and

$$\phi(x,y) = \begin{cases} 0 \\ e^{-\frac{\pi}{\lambda R} (x^2 + y^2)} \end{cases} \quad (10)$$

The other calculations based on input distributions are performed in subroutines.

c. Fortran -- The only common variables that are not altered in this routine are SPACE and CFIL. The others are altered and are defined as follows:

CU = the complex field array  
 X = the coordinate array  
 DRX = the x position of the optical axis  
 DRY = the y position of the optical axis  
 NPTS = the number of points in the x direction  
 NPY = the number of points in the y direction  
       = NPTS if SYMTRC is false  
       = NPTS/2 if SYMTRC is true  
 WL = the wavelength of the radiation  
 PLTSG = plotting parameter (none, amplitude, or intensity)  
 INT = set to 0

The relevant parameters are read into the program by means of the namelists described below.

(1) Namelist START -- This namelist is used to initialize parameters such as field, mesh, and coordinates, and is used to direct the calculation to other sections of SOQ. It is read repeatedly until WWL  $\leq$  0 is encountered.

## 2. SUBROUTINE LIST80

Calls: N/A

Called by: MAIN

Subroutine LIST80 is called by the executive routine MAIN to list data input to the SOQ code. The LIST80 flow chart (Fig. 13) appears on page 45.

After control is passed to LIST80, header information is printed. The input unit is read and a counter, KARD, is incremented for each record read. The input data is reformatted and printed on the line printer. When an end-of-file is received from the input unit, it is backspaced K records and control is returned to MAIN.

### Arguments

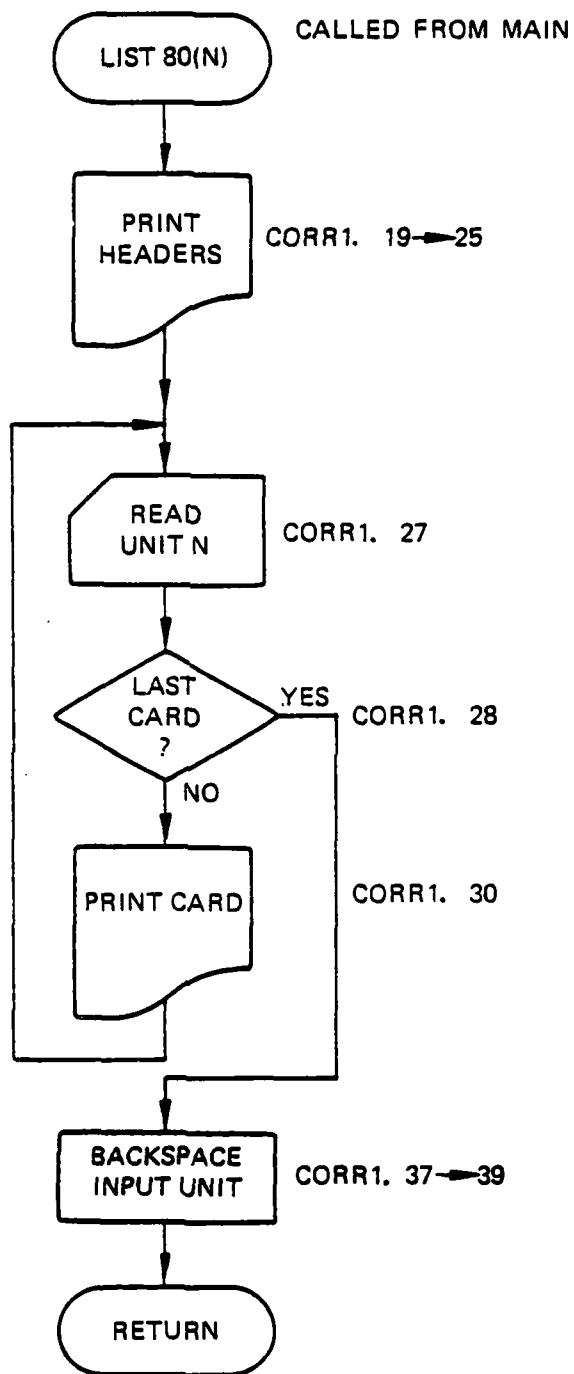

K Unit number on which input is read (usually 5).

### Relevant Variables

C Card inputs read and printed as read.

Figure 13. Subroutine LIST80 flow chart.

### 3. SUBROUTINE AEROW

Subroutine AEROW is used to apply a random phase variation to the complex field. Figure 14 shows the subroutine AEROW flow chart.

AERO is entered with the complex field array real coefficients, CUR, and with the number of points in x and y.

SIGMAM is a constant established by previous aerowindow work. It is later multiplied by the random number returned from the RANDU call to give the proper random phase range for an aerowindow.

Inside the DO LOOP, the random phase is obtained and the sine and cosine of the negative of this phase is taken. A negative number is required to yield a diverging phase impact.

The complex field, CU, is represented by a complex number,  $a + ib$ , whereas the CUR variables represent the real coefficients alone.

$$CU(1) \quad \begin{cases} CUR(1) = a \\ CUR(2) = b \end{cases} \quad a + ib \quad (11)$$

The random phase is applied by:

$$\overbrace{(a + ib)}^{CU} * e^{i\phi} \quad (12)$$

$$(a + ib) (\cos \phi + i \sin \phi) \quad (13)$$

$$\left. \begin{array}{l} a \cos \phi - b \sin \phi \rightarrow CUR(1) \\ b \cos \phi + a \sin \phi \rightarrow CUR(2) \end{array} \right\} \quad CU(1) \quad (14)$$

#### Argument List

CUR	Complex field array
NPTS	Number of x points
NPY	Number of y points

	END	RANDU	11

Figure 15. Subroutine RANDU flow chart.

5. SUBROUTINE APRTR

Called by: MIRROR, GDL

Calls: N/A

a. Purpose -- Subroutine APRTR applies an aperture, either circular or rectangular (Fig. 16), with or without a central obscuration, to the complex field. It also determines the value and position of maximum intensity on the aperture plate. Figure 17 shows the APRTR flow chart.

Figure 16. Subroutine APRTR nomenclature.

APRTR is entered with the inner and outer obscuration dimensions along with the coordinates of the aperture.

A test is made to see if the aperture is rectangular or circular. The appropriate boundary parameters are computed. Each point in the complex field is checked to see if it will pass through the clear aperture. If so, it is left alone. If not, it is zeroed out after it has been checked to determine if it is the location of maximum intensity on the aperture plate.

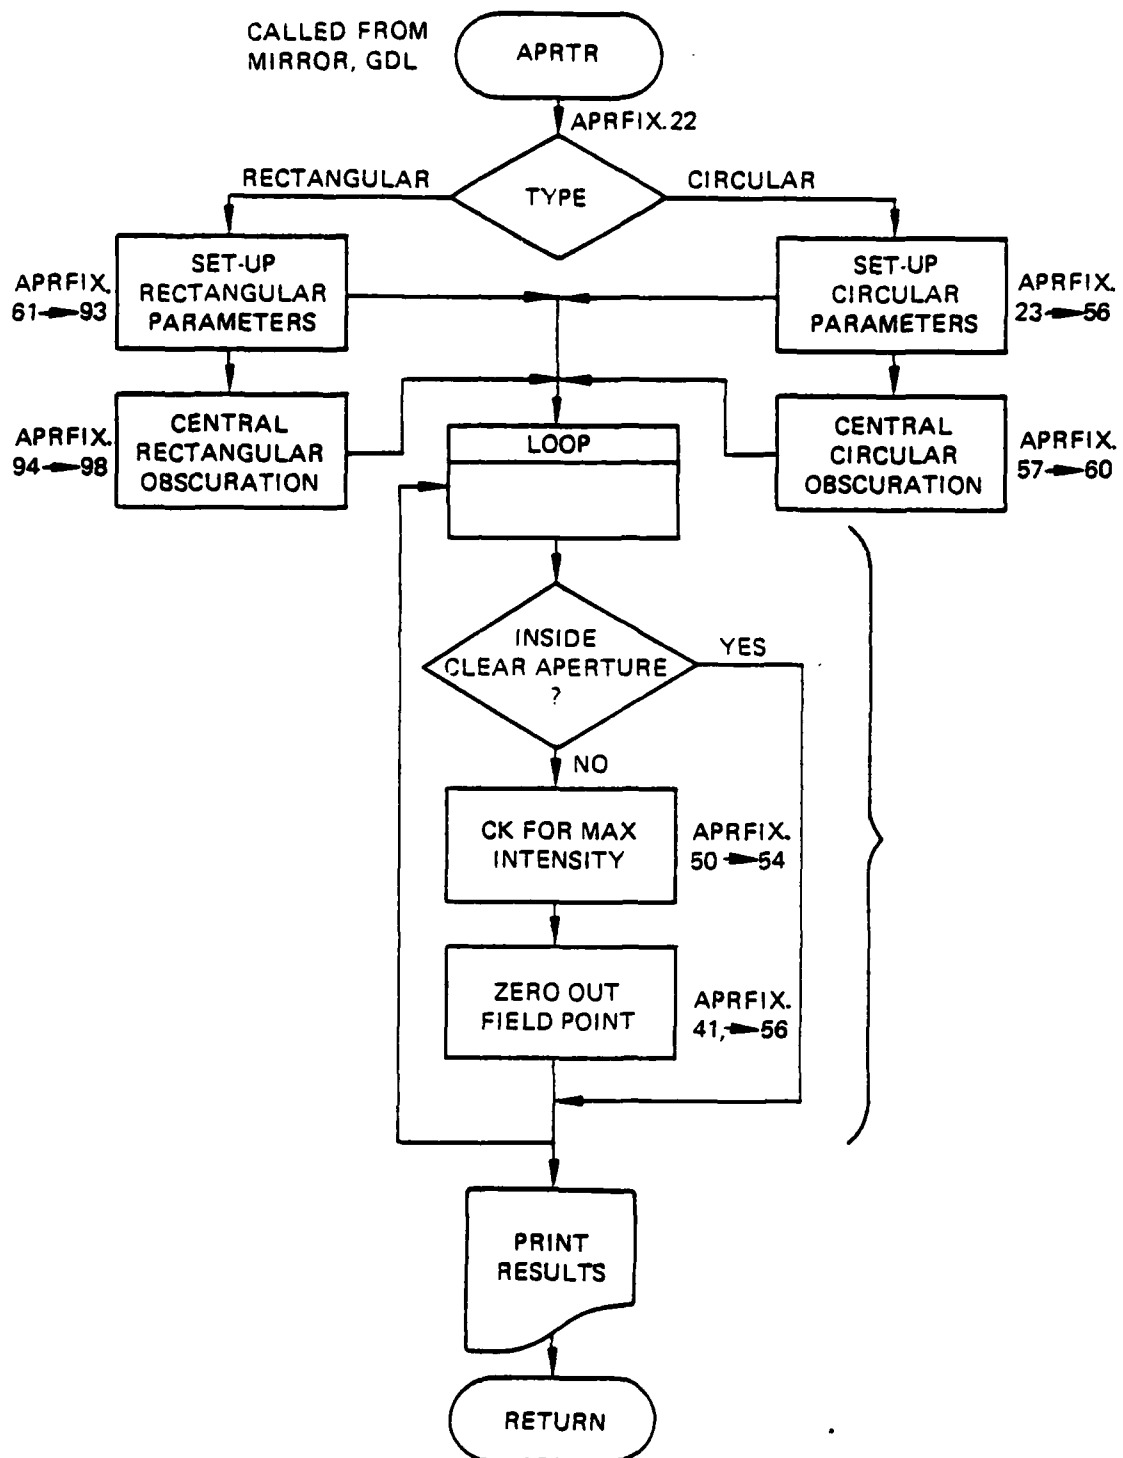

Figure 17. Subroutine APRTR flow chart.

The transmission function is

$$t(x, y) = \begin{cases} \text{RDISK} \leq \sqrt{(x-x_{\text{pos}})^2 + (y-y_{\text{pos}})^2} \leq \text{RAPRTR} \\ 0 \text{ otherwise} \end{cases} \quad (15)$$

b. Relevant formalism

$$\text{RPP} = \left( |x| + \frac{dx}{2} \right)^2 + \left( |y| + \frac{dy}{2} \right)^2 \quad (16)$$

$$\text{RMM} = \left( |x| - \frac{dx}{2} \right)^2 + \left( |y| - \frac{dy}{2} \right)^2 \quad (17)$$

$$\text{RMP} = \left( |x| - \frac{dx}{2} \right)^2 + \left( |y| + \frac{dy}{2} \right)^2 \quad (18)$$

$$\text{RPM} = \left( |x| + \frac{dx}{2} \right)^2 + \left( |y| - \frac{dy}{2} \right)^2 \quad (19)$$

These four locations represent an area surrounding the particular point of interest as shown in Figure 16. For each of these sets of points the locations of the aperture and obscuration are checked. If all the four points impinge on an aperture or central obscuration, then the intensity at that location is computed and checked for maximum value, then the field is zeroed out (by the impingement).

$$\text{Int} = (\text{ReCu})^2 + (\text{ImCu})^2 \quad (20)$$

$$\text{Max Int} = \text{AMAX} (\text{Int}, \text{Max Int}) \quad (21)$$

$$\text{PER} = 0 \quad (22)$$

$$\text{Cu} = \text{CU} \times \text{PER} \quad (23)$$

If all four points lie within the clear aperture, the field is unchanged.

$$\text{PER} = 1 \quad (24)$$

$$\text{CU} = \text{CU} \times \text{PER} \quad (25)$$

If the four points encompass an aperture edge, then the intensity is prorated on a percentage basis and transmitted.

$$\text{PER} = (\text{RAD} - \text{RMIN}) / \text{RMAX} - \text{RMIN} \quad (26)$$

$$\text{CU} = \text{CU} \times \text{PER} \quad (27)$$

where

$$\text{RMAX} = \text{MAX of (RPP, RMM, RMP, RPM)} \quad (28)$$

$$\text{RMIN} = \text{MIN of (RPP, RMM, RMP, RPM)} \quad (29)$$

$$\text{RAD} = \text{Radius (or x or y dimension) at aperture edge} \quad (30)$$

#### Argument List

RAPRTR	Radius of circular aperture (cm) or x-dimension (half width) of rectangular aperture (cm)
RDISK	Radius of central obscuration of a circular aperture (cm); or x-dimension (half width) of a rectangular central obscuration
XPOS	x location of aperture center with respect to optic center-line (cm)
YPOS	y location of aperture center with respect to optic center-line (cm)
YAPRTR	y dimension (half height) of rectangular aperture (cm)
YDISK	y dimension (half height) of a rectangular central obscuration (cm).

# Relevant Variables

A Half width of rectangular aperture (cm)  
 AINT Intensity ( $W/cm^2$ )  
 AINTMX Maximum intensity ( $W/cm^2$ )  
 B Half height of rectangular aperture (cm)  
 DX x distance between points in the mesh (cm)  
 DY y distance between points in the mesh (cm)  
 RAD = RAPRTR, aperture radius (cm)  
 X x location adjusted for centerline difference and accumulated dx (cm)  
 XAR (N) x or y position of N (cm)  
 Y y location adjusted for centerline difference and accumulated dy (cm).

## 6. SUBROUTINE BLUMIT

a. Purpose -- In the interstage duct, phase perturbation can be induced in the beam due to transient thermal blooming. This effect is suppressed by a sonic purge flow using the transverse thermal blooming routine. The BLUMIT routine models this residual sonic purge flow thermal blooming in the interstage duct. Figure 18 shows the subroutine BLUMIT organization.

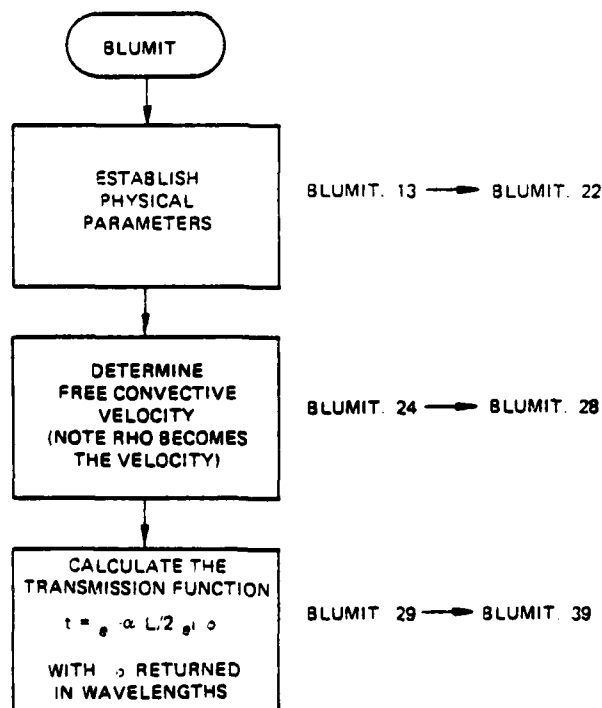

Figure 18. Subroutine BLUMIT organization.

b. Formalism -- As the beam propagates through the sonic purge flow, it is continuously distorted by that flow. Under the assumption that this distortion has a perturbative effect on the beam, the integrated effect of any thermal blooming can be approximated by a finite number of discrete steps in the following manner:

Assume each step is of length  $DL$ . The distortion is applied by propagating a length  $DL/2$  to the center of the cell, then applying the thermal blooming transmission function. The beam is then propagated through the remaining  $DL/2$  to the edge of the cell. The nonlinear blooming transmission function  $t(x,y,\Delta L, I(x,y))$  is

$$t(x,y,\Delta L, I(x,y)) = e^{-\alpha \Delta L / 2} e^{i \Delta \phi} \quad (31)$$

where,  $\alpha$  is the absorptivity of the medium.  $\Delta \phi$  is written

$$\Delta \phi = \frac{2\pi}{\lambda} \frac{dn}{dT} \int_0^{\Delta L} dz' \delta T(x,y,z') \quad (32)$$

This can be rewritten using the equation of state for an ideal gas ( $P = RT_0/M$ ) and the Gladstone-Dale relationship. Assuming constant pressure, the expression of  $\Delta \phi$  becomes

$$\Delta \phi = \frac{2\pi}{\lambda} \left( - \frac{\rho C_{G-D}}{T} \right) \int_0^{\Delta L} dz' \delta T(x,y,z') \quad (33)$$

where  $\delta T$  represents the temperature variation in the flow due to heating by the beam. For transverse blooming,  $\delta T$  can be written

$$\delta T = \frac{\alpha}{\rho C_p v_T} \int_{-\infty}^x dx' I(x',y,z) \quad (34)$$

In the above expression, the flow is assumed to be from the negative  $x$  direction with speed  $v_T$ .

This effect is activated in subroutine CAVITY by setting NGTYPE=2. The duct is then treated as if it were another cavity, the gain/phase transmission function being that of transverse thermal blooming. It is updated by subroutine REGAIN.

Since the only mathematical difference between transverse and free convective is in the velocity, this routine can also handle free convection blooming with

$$v_{fc} = \left( \frac{2\alpha P(z)g}{\rho C_p T} \right)^{1/3} \quad (35)$$

c. Fortran

#### Argument list

P = Intensity array. It returns as the phase change in wavelengths due to blooming.

G = Gain array. Intensity loss due to blooming.

NCV = Cavity number

WL = Wavelength

## 7. SUBROUTINE CAVITY

a. Purpose -- The CAVITY routine models the interaction of a GDL cavity and the complex optical field. As the simulated field is propagated through the cavity, it interacts with the flowing medium. As a result, both the intensity and phase of the beam are modified through the CAVITY routine. Figure 19 shows the subroutine CAVITY organization.

b. Formalism -- As the beam is propagated through the cavity, its intensity and phase are continuously updated. The beam's amplitude and phase are amplified and redirected by the medium-induced gain and phase change. This medium-beam interaction results in an integrated effect. It is assumed in CAVITY that the total effect can be approximated by a finite sum of N terms in the following manner: The total cavity length Z is divided into N steps, each  $Z/N = \Delta L$  in length. In each segment, the interaction of the field with the medium is approximated by vacuum propagation through half of the segment,  $(\Delta L/2)$ , followed by the application of a field dependent transmission function of the form

$$t(x,y,I) = \varepsilon^{\Delta L} \left[ g(x,y,I)/2 + i \frac{2\pi}{\lambda} (\Delta n(x,y,I)) \right] \quad (36)$$

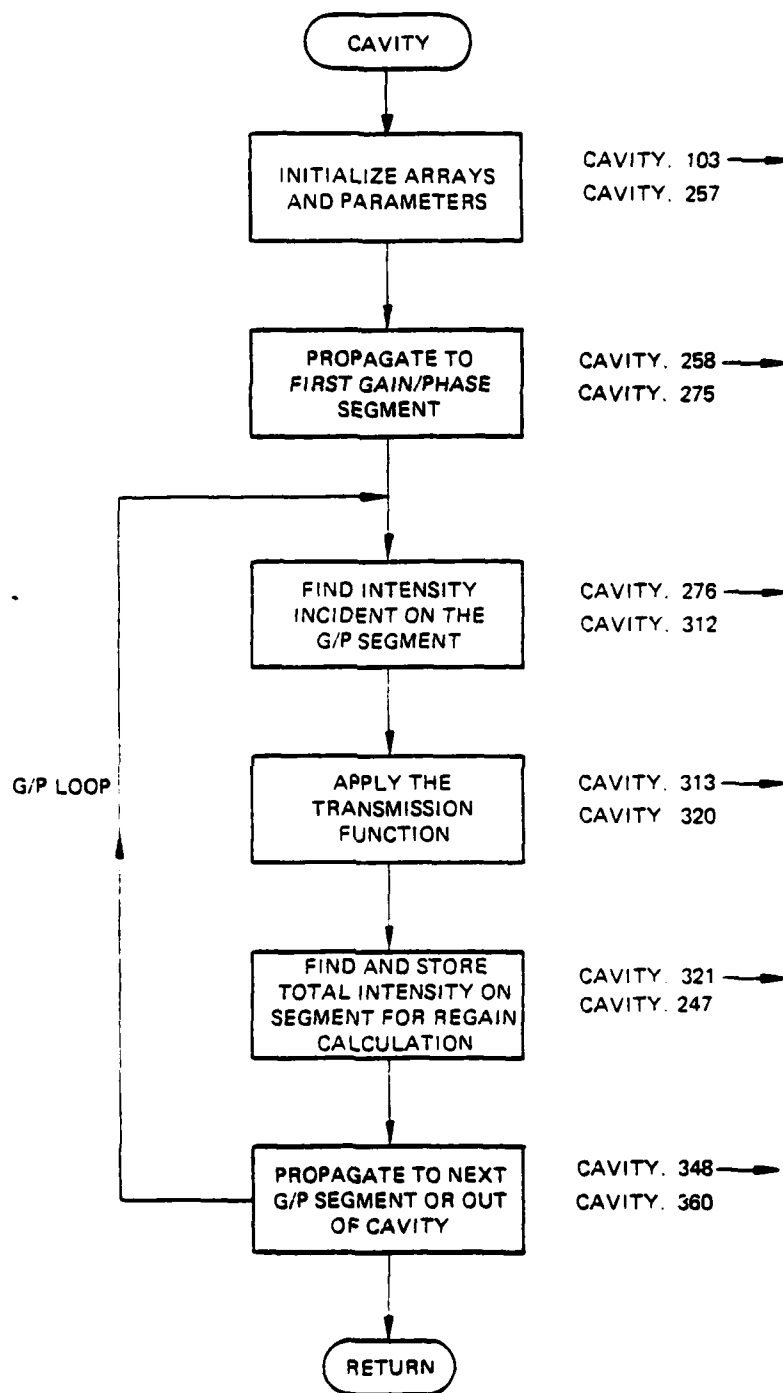

Figure 19. Subroutine CAVITY organization.

The gain coefficient  $g$  and refractive index  $\Delta n$  are calculated in other subroutines using an appropriate choice of kinetic modeling. The beam is then vacuum propagated through the remaining  $\Delta L/2$ . This procedure is repeated until the beam reaches the end of the cavity.

c. Fortran

Argument List

NCAV = Cavity identity number (1, 2, 3, ... N)

ILR = identifies the direction of propagation through the cavity:

-1 => right to left

+1 => left to right

NEWCAV = A parameter that identifies whether the cavity has been entered before.

INIT = .True. if it is the first interaction of a given run

= .False. if it is the second or subsequent interaction.

NSTE = Controlling parameter for subroutine STEP. If the geometric beam is converging or diverging, variable area mesh propagation (VAMP) should be used.

NSTE = 1 Constant mesh with setup

= 2 VAMP with setup (exit at end)

= 3 VAMP (setup and remain in VAMP)

= 4 VAMP (uses existing setup and exits)

= 5 VAMP (uses existing setup and does not exit)

IN = Input data set number or file from which data is to be read

RESTRT = .True. if initial beam is read in from unit IB

= .False. if analytical initial field is desired

NPLT = Controls plotting within cavity:

= 0 No plot

= 1 Print field before and after gain and gain coefficient

ZLI = Incoming propagation distance to cavity endwall

(Additional vacuum propagation distance)

ZLO = Exit propagation distance to cavity endwall

(Additional vacuum propagation distance)

Note: None of the parameters in the argument list is redefined by subroutine CAVITY.

Common variables altered:

- US - the intensity array
- PPD - interpolated power density
- CDUM - interpolated gain/phase transmission element
- XCAV - cavity coordinate array
- GFACT - define by namelist CAVTY2
- CFIL - redefined by its equivalence with Power Density array
- CU - the complex field - modified by propagation and the application of the cavity transmission function
- CG - defined for the first pass, read in for subsequent passes (Cavity gain/phase (G/P) array at each station within the cavity)

Namelist/CAVTY 2

CAVTY2 is used to initialize the cavity physical properties. The namelist is as follows:

```

NAMELIST/ CAVTY2 /XLEN,YLEN,ZLEN,XMCAV,YMCAV,NODX,NODY,NOSEG,

## 8. SUBROUTINE CENBAR

a. Purpose -- This subroutine is used by QUAL to find the centroid coordinates of the far-field beam. Figure 20 describes subroutine CENBAR organization.

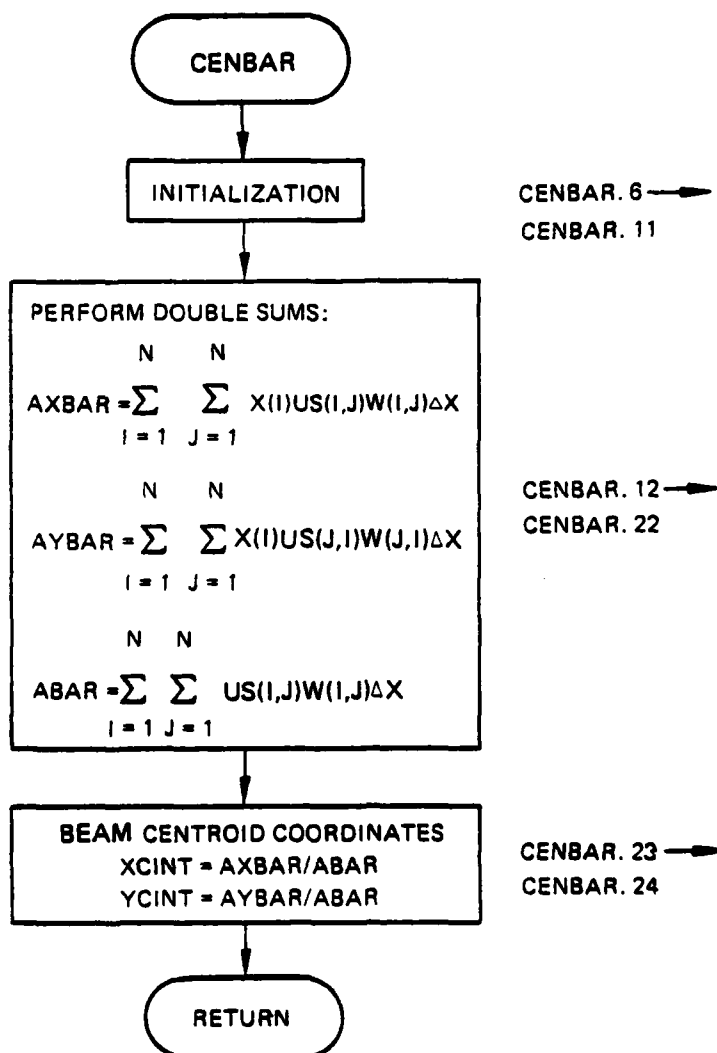

Figure 20. Subroutine CENBAR organization.

b. Formalism -- Let  $E(x,y)$  represent the field and let  $w(x,y)$  be a weighting function defined by

$$w(x,y) = \begin{cases} 1, & \text{if } |E(x,y)|^2 > 0.1 (|E|_{\max}^2) \\ 0, & \text{if } |E(x,y)|^2 \leq 0.1 (|E|_{\max}^2) \end{cases} \quad (37)$$

Then the intensity-weighted centroid coordinates are found from

$$\vec{x}_c = \frac{\iint dx dy |E(x,y)|^2 w(x,y) \vec{x}}{\iint dx dy |E(x,y)|^2 w(x,y)} \quad (38)$$

where the integrals are numerically evaluated over the calculation region.

c. Fortran

Argument List

NPTS = Number of points in x direction

DX = spacing between two adjacent points

X = coordinate array

US = intensity array =  $|CU(I)|^2 = |E(x,y)|^2$

XCINT = Centroid coordinate in the X direction }  $\vec{x}_c$   
YCINT = Centroid coordinate in the Y direction }

UMAX = Maximum Intensity

The incoming parameters are NPTS,DX,X,US,UMAX. They are unchanged by this routine and are used to calculate XCINT and YCINT.

Note: The subroutine assumes that the field is square. Computer printout of subroutine CENBAR follows.

## 9. SUBROUTINE DENSITY

Called from: CAVITY.

Calls: LINTERP, ROSN, ROSN6

a. Purpose -- This routine controls the generation of the cavity density-induced phase distortion for each cavity in the optical train. DENSITY provides a choice of density fields including interpreted test data from several devices and the ability to read in density fields from tape. Little formal calculation is done within the routine itself, other than the generation of multipliers and certain other constants used by the interpolation routines. DENSITY does tabulate spline coefficients if any are used to generate the phase distorting field, and provides a decile plot of the phase field. Figure 21 shows the subroutine DENSITY flow chart.

### Argument List

FLAG	flag for density field selection
IF	file number where MOD 6 density field is stored
IN	file number where input card data is stored
NPX	number of cavity density grid points in X direction
NPY	number of cavity density grid points in Y direction
NSYM	flag for symmetry of field
RHO	free stream static density
XLEN	X-dimension (flow direction) of cavity segment
YLEN	Y-dimension (sidewall-to-sidewall) of cavity segment
ZSLAB	Z-dimension (optical direction) of cavity segment

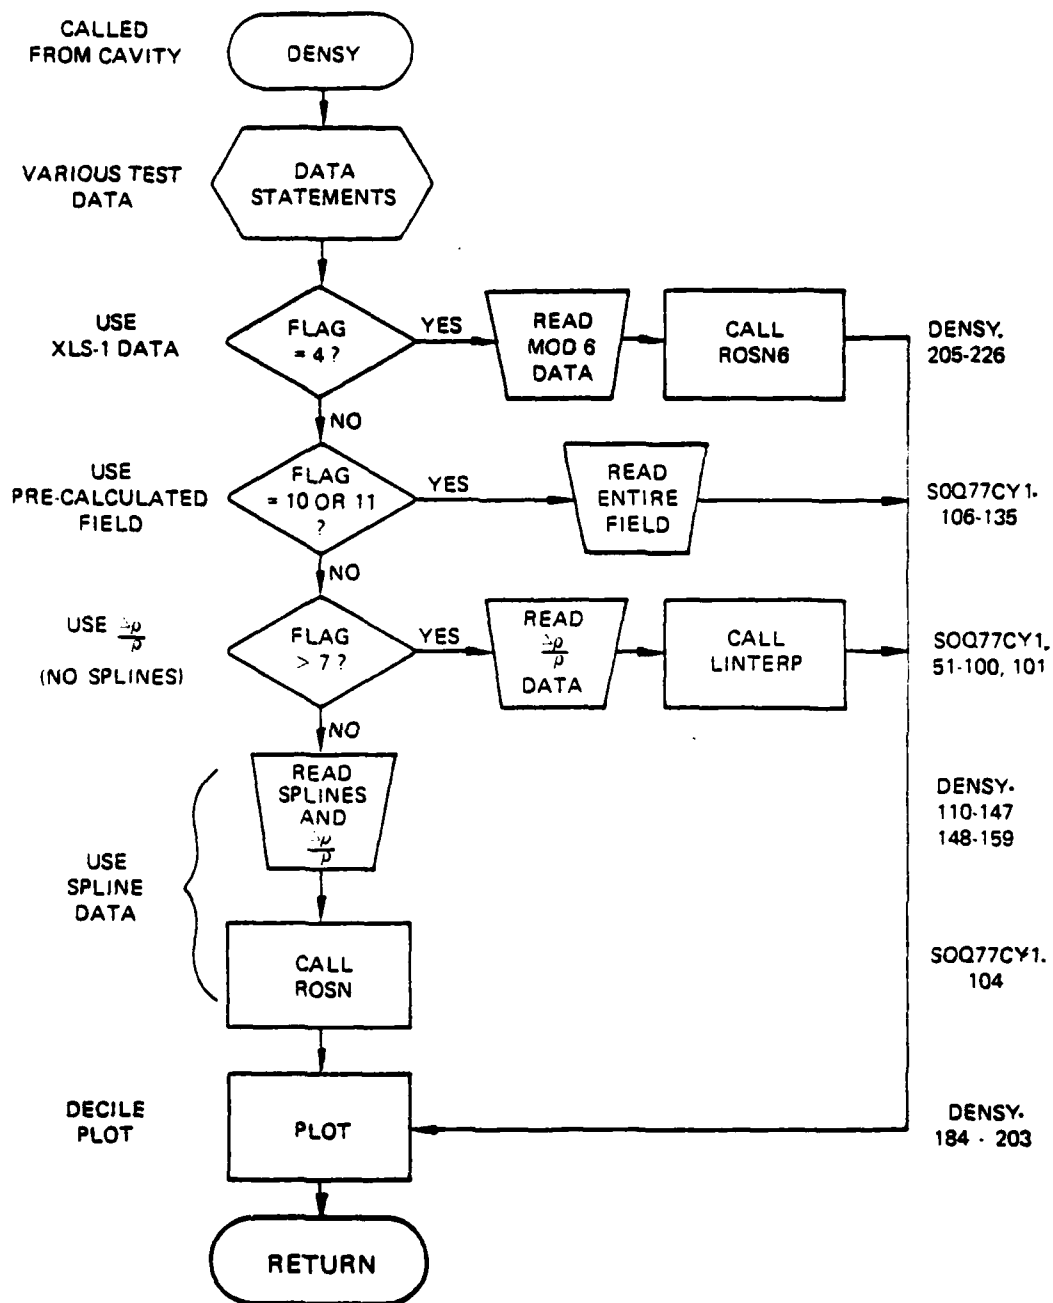

Figure 21. Subroutine DENSITY flow chart.

## Commons Modified

Z4	
C4	
M4	
N4	
ROCL	

/LENSY/

### Variables Modified

D	spline coefficient array
H	cavity width (sidewall-to-sidewall)
LL	flag for cavity wall symmetry
M	number of data points in spline arrays
RHOCL	centerline density variation
TITLE	field identified
TM	tangent of Mach angle
XLS	spline array center deviation from NEP
XMULT	magnifier for entire density field
Y	position array
Z	density change array

b. Relevant formalism -- Most of the formal calculations involving spline fitting a density field and interpolating the results are done external to DENSITY (see subroutines LINTERP, ROSN, and ROSN6). This routine directs the activities that generate the desired field. These activities are summarized below:

- (1) The density field is read in directly from information generated by another program and written to disk (FLAG = 10 or 11)

- (2) The sidewall density variations, but not the coefficients for a spline fit, are read in by NAMELIST or from data statements. The complete density field is generated by projecting these data into the flow along Mach lines, and linearly interpolating via LINTERP. (FLAG = 8, 8.1, 9, 9.1)
- (3) The sidewall density variations and their spline fit coefficients are read in on cards or taken from DATA statements. The complete density field is generated by interpolating with the spline fit along the projection. (FLAG = 1 through 7)

A decile plot of the density-induced optical path variation (in cm) is generated after returning from one of these actions.

Subroutine DENSITY computer printouts follow.

## 10. SUBROUTINE FOURT

a. Purpose -- Subroutine FOURT performs a forward or backward Fast Fourier Transform on any multidimensional complex array by efficiently performing the summation.

$$A_m = \sum_{N=0}^{N-1} X_n e^{\pm 2\pi i m n / N} \quad (39)$$

The transform pair that needs to be evaluated is

$$F(s) = \int_{-\infty}^{\infty} f(x) e^{2\pi i x s} dx \quad (40)$$

and

$$f(x) = \int_{-\infty}^{\infty} F(s) e^{-2\pi i x s} ds \quad (41)$$

To digitally evaluate an integral, the continuous form of an integral must be changed to its discrete form. For example,

$$G = \int_a^b g(x) dx \Rightarrow \lim_{N \rightarrow \infty} \sum_{n=0}^N g_n \Delta X \quad (42)$$

b. Relevant formalism -- Assume that all the intervals,  $\Delta X_n$ , are chosen to be equal and that the infinite sum can be approximated by a finite sum. Then,

$$G \approx \sum_{n=0}^{N-1} g_n (x_{n+1} - x_n) \text{ with } g_n = g \left( x = \frac{n(b-a)}{N} \right) \quad (43)$$

$$G \approx \sum_{n=0}^{N-1} g_n \left[ (n+1) \frac{(b-a)}{N} - n \frac{(b-a)}{N} \right]$$

or

$$G \approx \Delta X \sum_{n=0}^{N-1} g_n \int_a^b g(x) dx \quad (44)$$

To evaluate Equations (40) and (41) by the approximate form (Eq. (44)), assume that the function  $f(x)$  is spatially bounded in  $0 \leq x < 2L$  and that it is a band-limited function so that  $F(s)$  is confined in the region  $-B \leq s \leq B$ . To perform either a backward or forward Fourier transform, the functions  $f$  and  $F$  should differ in form only by the sign of the exponent. Therefore, the properties of  $F$  must be evaluated so that its region can be changed to  $0 \leq s \leq 2B$ . This is easily done by replicating the function  $f(x)$  so that it is periodic with period  $2L$ . This will not change the value of  $f$  in the region of interest and, by proper choice of  $N$ , will return the desired function  $F$ .

A sampled function,  $f_s$ , can be analytically represented by a Dirac delta function:

$$f_s(x) = \sum_{n=0}^{N-1} f_n \delta(x - n\Delta x) \text{ with } \Delta x = \frac{2L}{N} \quad (45)$$

A replicated function can be represented by a convolution:

$$\begin{aligned} f_{\text{rep}}(x) &= \int_0^{2L} dx' f(x') \sum_{n=-\infty}^{\infty} \delta(x - (x' + 2LN)) \\ &= f(x) \sum_{n=-\infty}^{\infty} \delta(x - n2L) \end{aligned} \quad (46)$$

Therefore, a sampled and replicated function is represented by:

$$\hat{f}(x) = \sum_{n=0}^{N-1} f_n \delta(x - n\Delta x) \sum_{m=-\infty}^{\infty} \delta(x - mN\Delta x) \quad (47)$$

The Fourier Transform  $\hat{F}(s)$  of  $\hat{f}(x)$  is

$$\hat{F}(s) = F\{\hat{f}\} = F\left\{\sum_{n=0}^{N-1} f_n \delta(x - n\Delta x)\right\} F\left\{\sum_{m=-\infty}^{\infty} \delta(x - mN\Delta x)\right\} \quad (48)$$

by the convolution theorem. Since

$$\sum_{n=-\infty}^{\infty} \delta(x-na) = \frac{1}{a} \sum_{n=-\infty}^{\infty} e^{2\pi i n \frac{x}{a}} \quad (49)$$

one finds,

$$\hat{F}(s) = \sum_{n=0}^{N-1} f_n e^{2\pi i s n \Delta x} \sum_{m=-\infty}^{\infty} \frac{1}{N \Delta x} \delta\left(s - \frac{n}{N \Delta x}\right) \quad (50)$$

Rearranged this gives

$$\hat{F}(s) = \frac{1}{N \Delta x} \sum_{m=-\infty}^{\infty} \delta\left(s - \frac{m}{N \Delta x}\right) \sum_{n=0}^{N-1} f_n e^{2\pi i m n / N} \quad (51)$$

Recalling Equations (40) and (44), define

$$F_n = \Delta x \sum_{n=0}^{N-1} f_n e^{2\pi i n m / N} = F_{n+N} \quad (52)$$

Then

$$\hat{F}(s) = \frac{1}{N(\Delta x)^2} \sum_{m=-\infty}^{\infty} F_m \delta\left(s - \frac{m}{N \Delta x}\right) \quad (53)$$

Since  $F_m = F_{m+N}$ , one can rewrite the above as a replication for every  $N$  point.

$$\hat{F}(s) = \frac{1}{N(\Delta x)^2} \sum_{m=0}^{N-1} F_m \delta\left(s - \frac{m}{N \Delta x}\right) \sum_{n=-\infty}^{\infty} \delta\left(s - \frac{n}{\Delta x}\right) \quad (54)$$

Therefore, by replicating  $f(x)$  with period  $2L$ ,  $F$  is periodic with period  $1/\Delta x$ .

So by choosing  $N$  so that  $N/2L \geq 2B$ , rewrite the limits for  $F$  as  $0 \leq S \leq B$ .

Since

$$\delta_{nk} = \frac{1}{N} \sum_{m=0}^{N-1} e^{2\pi i m(n-k)/N} = \begin{cases} 1, & n = k \\ 0, & n \neq k \end{cases} \quad (55)$$

invert (52) to find

$$f_n = \frac{1}{N\Delta x} \sum_{m=0}^{N-1} F_m e^{-2\pi i m n/N} \quad (56)$$

Thus, choosing  $\Delta s = 1/N\Delta x$ , the transform pair becomes

$$F_m = \Delta x \sum_{n=0}^{N-1} f_n e^{-2\pi i m n/N} \quad (57)$$

$$f_n = \Delta s \sum_{m=0}^{N-1} F_m e^{-2\pi i m n/N} \quad (\Delta x \Delta s = \frac{1}{N}) \quad (58)$$

where, with  $N/2L \geq 2B$ ,  $F_m$  represents  $F(s)$  for  $0 \leq S_m \leq 2B$  ( $S_m = m\Delta s$ ) and  $f_n$  represents  $f(x)$  for  $0 \leq x_n \leq 2L$  ( $x_n = n\Delta x$ ).

The transform pair  $f_n$  and  $F_m$  are now in a form usable by the Fast Fourier Transform (FFT). The FFT evaluates the sum

$$A_r = \sum_{k=0}^{N-1} X_k e^{\pm 2\pi i r k/N} \quad (59)$$

Following Higgins (Ref. 9), this sum can be split into two sums (choosing the + sign in the exponent):

$$A_r = \sum_{\substack{k=0 \\ (\text{keven})}}^{N-1} x_k e^{\pi i r k / N} + \sum_{\substack{k=0 \\ (\text{kodd})}}^{N-1} x_k e^{2\pi i r k / N} \quad (60)$$

Let

$$k = 0, 1, 3, 5, \dots \frac{N}{2} - 1 \quad (61)$$

then

$$A_r = \sum_{k=0}^{\frac{N}{2}-1} \left[ y_k e^{2\pi i r 2k / N} + z_k e^{2\pi i r (2k+1) / N} \right] \quad (62)$$

Letting

$$B_r \equiv \sum_{k=0}^{\frac{N}{2}-1} y_k e^{4\pi i r k / N} \quad (63)$$

and

$$C_r \equiv \sum_{k=0}^{\frac{N}{2}-1} z_k e^{4\pi i r k / N} \quad (64)$$

9. Wiggins, R.J., "Fast Fourier Transform: An Introduction With Some Minicomputer Experiments," AJP, 44, 1976.

$A_r$  can be written

$$A_r = B_r + C_r e^{2\pi i r/N} \quad (65)$$

Define

$$W_n \equiv e^{2\pi i/N} \quad (66)$$

Then,

$$A_r = B_r + C_r + (W_n)^r \quad (67)$$

By letting  $r \rightarrow r + N/2$ :

$$A\left(r + \frac{N}{2}\right) = B_r - (W_n)^r C_r \quad (68)$$

Therefore,  $A_r$  can be evaluated by doing two sums, each containing  $N/2$  terms. However, these sums need to be performed for only half the  $r$ 's  $\left(0 \leq r < \frac{N}{2}\right)$  since  $A_{r + N/2}$  is found using the two sums used in the evaluation of  $A_r$ . By

initially forcing  $N$  to be a power of two by completing the array to be transformed with zeros, continue to divide each successful sum into two, until a "sum" is reduced to just one number, taking care to note that  $N$  changes with each division. When using the FFT, care must be taken to scale the output correctly since the FFT evaluates only sums of the form

$$A_r = \sum_{n=0}^{N-1} x_n e^{\pm 2\pi i n r/N} \quad (69)$$

and as can be seen from Equations (58) the Fourier Transforms contain  $\Delta x$  or  $\Delta s$ : If only forward then backward transforming is done, it is sufficient to divide the final answer by  $N$  for each dimension as is indicated by the last part of Equation (58).

Note that when the data are returned from the FFT the first data point is either the  $x = 0$  or the  $s = 0$  point. To see the actual frequency space pictures, assume a two-dimensional case. An isointensity printer plot of FFT output in frequency space might look like that shown in Figure 22.

Figure 22. Example of isointensity printer plot of FFT output in frequency space.

To see the  $-B$  to  $+B$  version, the adjacent cells shown in Figure 23 must be added to Figure 22.

The subroutine FOURT computer printouts follow.

Figure 23.  $-B$  to  $+B$  version of isointensity printer plot of FFT output in frequency space.

## 11. SUBROUTINE FUHS

a. Purpose -- Subroutine FUHS is used to calculate the phase change due to heat release as the molecules in the lower laser level decay to the ground state, assuming supersonic flow and that the heat release has a disturbing effect (not major) on the flow. Figure 24 shows the subroutine FUHS flow chart.

b. Relevant formalism -- The equations used are based on those by Biblarz and Fuhs, (Ref. 10), and by Fuhs (Ref. 11).

Initially, it is assumed that the continuity, momentum, and energy equations for steady flow with heat addition are valid:

$$\text{Continuity: } \nabla \cdot (\rho \vec{u}) = 0 \quad (70)$$

$$\text{Momentum: } \rho \frac{D\vec{u}}{Dt} + \vec{\nabla} p = 0 \quad (71)$$

$$\text{Energy: } \nabla \cdot \rho \vec{u} \left( h + \frac{\vec{u}^2}{2} \right) = q \quad (72)$$

These are linearized, assuming

$$\rho = \rho_\infty + \rho' \quad p = p_\infty + p' \quad \vec{u} = \hat{i} (U + u') + \hat{j} v' \quad (73)$$

resulting in

$$\text{Continuity: } \rho_\infty u'_x + \rho_\infty U'_y + U \rho'_x = 0 \quad (74)$$

$$\left( u' \equiv \frac{\partial}{\partial x} u' ; \text{ etc.} \right) \quad (75)$$

$$\text{Momentum: } \left\{ \begin{array}{l} \rho_\infty U u'_x + p'_x = 0 \\ \rho_\infty U v'_x + p'_y = 0 \end{array} \right\} \quad (76)$$

10. Biblarz, O. and Fuhs, A. E., "Laser Cavity Density Changes with Kinetics of Energy Release," AIAA Journal, 12, p. 1083, August 1974.

11. Fuhs, A. E., "Quaside Area Rule for Heat Addition in Transonic and Supersonic Flight Regimes," AFAPL-TR-72-10, Air Force Propulsion Laboratory, WPAFB, Ohio, 1972.

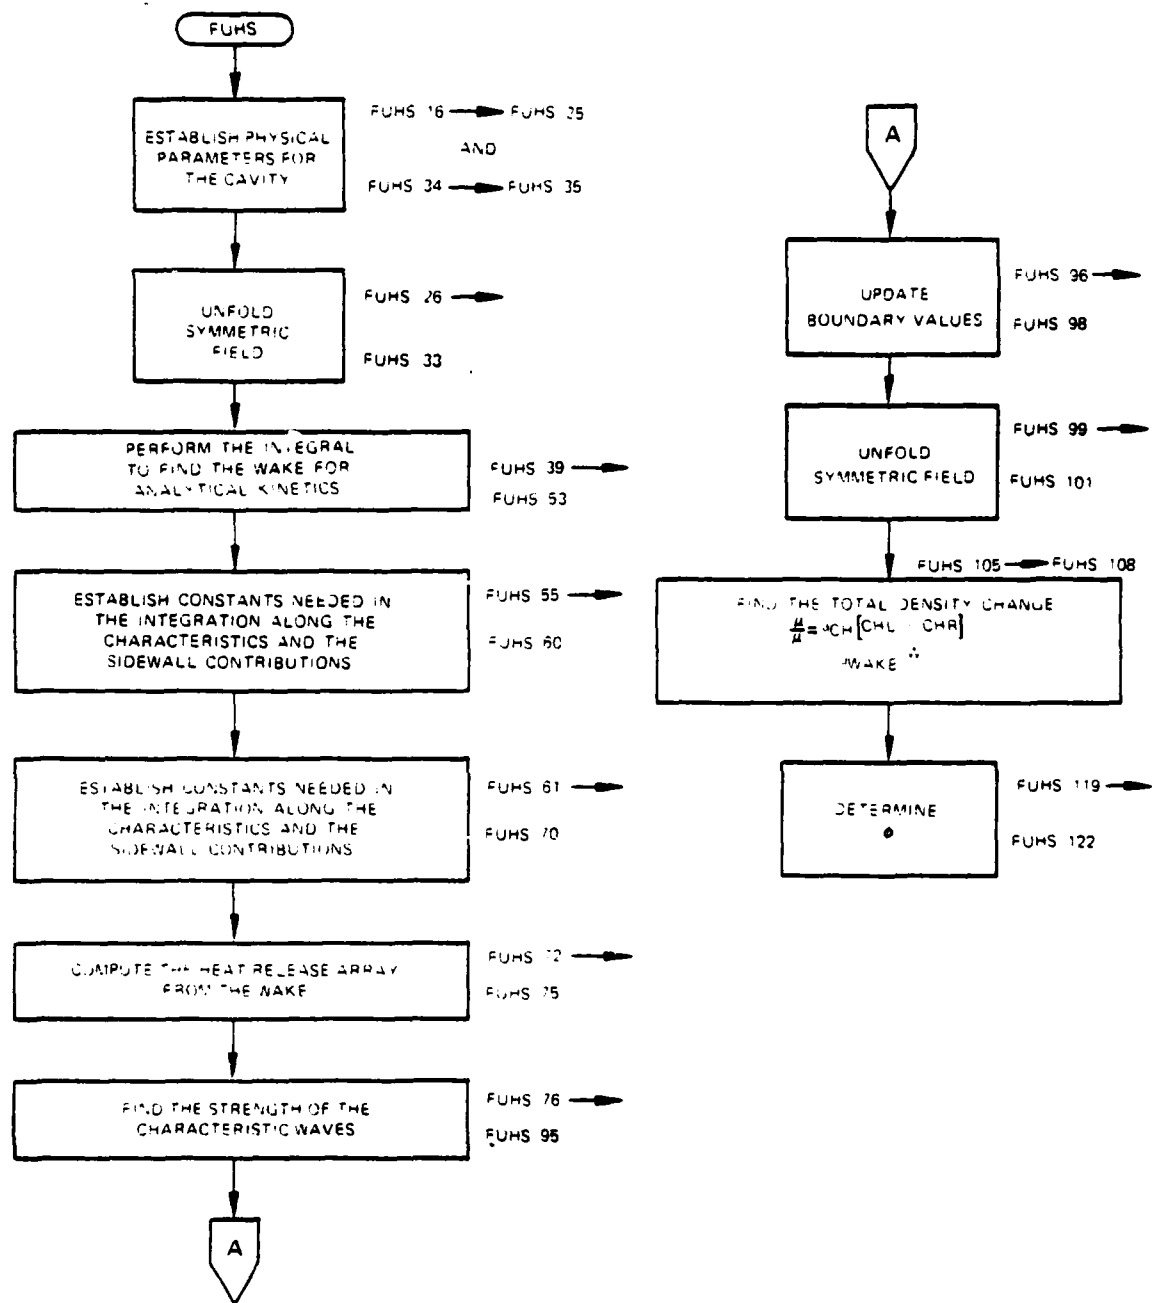

Figure 24. Subroutine FUHS organization.

$$\text{Energy: } \frac{\rho_{\infty} U_{\infty}}{\gamma-1} \frac{\partial}{\partial} \left( \frac{p'}{p_{\infty}} - \frac{\gamma \rho'}{\rho_{\infty}} \right) = q \quad (77)$$

The solution is then found by using the potential for the flow as done by Tsien and Bielloch, (Ref. 12), resulting in the following equations for a heat source  $q$  in supersonic heat addition

$$u' = - \frac{(\gamma-1)q}{2\gamma\rho\beta} \delta(x-\beta y) \quad (78)$$

$$v' = \frac{(\gamma-1)q}{2\gamma\rho} \delta(x-\beta y) \quad (79)$$

$$p' = \frac{(\gamma-1)qM}{2a\beta} \delta(x-\beta y) \quad (80)$$

$$\rho' = \frac{(\gamma-1)qM}{2a^3\beta} \delta(x-\beta y) - \frac{(\gamma-1)q}{a^2U} \delta(y) I(x) \quad (81)$$

where

$$x = \beta y \quad \text{Defines a Mach line} \quad (82)$$

$$\beta = \sqrt{M^2-1} \quad (83)$$

$$a = U/M \quad \text{Speed of sound} \quad (84)$$

$$I(x) = \begin{cases} 1, & x > 0 \\ 0, & x < 0 \end{cases} \quad (85)$$

For volume heat addition  $q \rightarrow dq = h(x,y)dxdy$ , and the effect of all sources are added; for example,

$$u' = \frac{-(\gamma-1)}{2\gamma\rho\beta} \iint h(x,y) dxdy \delta(x-\beta y) \quad (86)$$

$$= \frac{-(\gamma-1)}{2\gamma\rho\beta} \int_0^s h(x=\beta y) \sin \mu ds \quad (87)$$

12. Tsien, H. E. and Milton Beilock, "Heat Source in a Uniform Flow," Journal of the Aeronautical Sciences, December 1949, p. 746.

where the integral is taken along a streamline ( $x = \beta y$ ) and  $\sin \mu = 1/M$ .  $S$  is related to  $x$  and  $y$  by

$$S = x \cos \mu \quad S = y \sin \mu$$

The equation for density change is therefore,

$$\frac{\Delta \rho}{\rho} = \frac{1}{\rho} \left[ \left( \frac{\gamma-1}{2a^3 \beta} \int_0^S h(x,y) \Big|_{x=\beta y} \sin \mu ds \right) - \left( \frac{\gamma-1}{a^2 U} \iint dx' dy' h(x',y') \delta(y-y') I(x-x') \right) \right] \quad (88)$$

The first term is due to heat addition along a streamline while the second is due to the wake in the energy release region. "Heat addition in a supersonic stream causes compression waves which radiate from the heat release region. The waves reflect from the cavity walls. Downstream of the heat release region is a wake. Whereas the compression waves increase gas density the wake decreases gas density" (Ref. 12).

The heat release ( $h(x,y)$ ) for a laser can be written:

$$h(x,y) = c \int_{x_{NEP}}^x \Delta I(x',y) e^{-(x-x')/UT} dx' \quad (89)$$

where  $T$  is the time constant for the depopulation of the lower laser level. If the depopulation were instantaneous ( $T \rightarrow 0$ ) then the heat release would be proportional to the intensity since for every molecule emitting a photon, that same molecule gives off a quantum of heat. It has been shown (Ref. 12) that the above equation for the heat release can be used in all regions of the far cavity with only small error.

The constant  $C$  can be found by conservation of energy. Consider the following three-level molecule shown in Figure 25.

Figure 25. Three-level molecule.

The quantum efficiency  $\eta$  is defined as the ratio of the power out divided by the power in, so for the gain/phase segment under consideration

$$\eta = \frac{(\text{No. molecules}) (E_2 - E_1)}{(\text{No. molecules}) (E_2 - E_0)} = \frac{P}{\Delta H + \Delta P} \quad (90)$$

where

$$\Delta H = (\text{No. molecules}) (E_1 - E_0)$$

The above expression can be inverted to give

$$\Delta H = \left( \frac{1-\eta}{\eta} \right) \Delta P$$

with

$$\Delta P = \iint dx dy' \Delta I(x', y')$$

and

$$\Delta H = \iint dx dy' h(x', y') \quad (91)$$

Assume, for this calculation, that  $(0,0)$  is at the corner of the sidewall and the NEP. Then,

$$\begin{aligned} \Delta H &= c \Delta z \int_0^\infty dy \int_0^\infty dx \int_0^\infty \Delta I(x', y) e^{-(x-x')/UT} dx' \\ &= c \Delta z \int_0^\infty dy \int_0^\infty dx \int_0^\infty I(x-x') \Delta I(x', y) e^{-(x-x')/UT} dx' \end{aligned} \quad (92)$$

where, recall

$$I(x-x') = \begin{cases} 1, & x > x' \\ 0 & x < x' \end{cases}$$

so

$$\begin{aligned} \Delta H &= c\Delta z \int_0^\infty dy \int_0^\infty dx \Delta I(x', y) \int_0^\infty dx I(x-x') e^{-(x-x')/UT} \\ &= c\Delta z \int_0^\infty dy \int_0^\infty dx \Delta I(x, y) \int_{x'}^\infty dx e^{-x''/UT} \end{aligned} \quad (93)$$

$$\begin{aligned} \Delta H &= c\Delta z \int_0^\infty dy \int_0^\infty dx \Delta I(x, y) \left( \frac{1}{1/UT} \right) \\ &= cUT\Delta z\Delta P \end{aligned} \quad (94)$$

so

$$\frac{1-\eta}{\eta} = \frac{\Delta H}{\Delta P} = cUT\Delta z \quad (95)$$

or

$$c = \left( \frac{1-\eta}{\eta} \right) \left( \frac{1}{UT\Delta z} \right) \quad (96)$$

Since the numerical kinetics return the conditions of the wake region and not the heat addition, these must be the data used. Thus, for the analytical kinetics model, find the heat addition to the wake:

$$\begin{aligned}
W(x,y) &= \int_0^x dx' h(x',y) = c \int_0^x dx' \int_0^{x'} dx'' \Delta I(x'',y) e^{-(x'-x'')/UT} \\
&= c \int_0^\infty dx' I(x-x') \int_0^\infty dx'' I(x'-x'') \Delta I(x'',y) e^{-(x-x'')/UT} \\
&= c \int_0^\infty dx'' \Delta I(x'',y) \int_0^\infty dx' I(x-x') I(x'-x'') e^{-(x'-x'')/UT} \\
&= c \int_0^\infty dx'' \Delta I(x'',y) I(x-x'') \int_{x''}^x dx' e^{-(x'-x'')/UT} \quad (97)
\end{aligned}$$

so

$$W(x,y) = c \int_0^x dx'' \Delta I(x'',y) UT \left( 1 - e^{-(x-x'')/UT} \right) \quad (98)$$

so, recalling

$$c = \frac{1-\eta}{\eta} \frac{1}{UT\Delta z} \quad \text{and} \quad \Delta I(x'',y) = 2 \left( \frac{1-G}{1+G} \right) \text{PPD from SIMPGC} \quad (99)$$

wake energy addition becomes

$$W(x,y) = \frac{2}{\Delta z} \left( \frac{1-G}{1+G} \right) \frac{1-\eta}{\eta} \int_0^x dx' \text{PPD}(x',y) \left( 1 - e^{-(x-x')/UT} \right) \quad (100)$$

Now that both numerical and analytical models can give the wake integrated heat addition, the Fuhs effect is calculated in the following manner:

$$H(I,J) = \frac{1}{\Delta x} \int_{x(I-1)}^{x(I)} h(x,y) dx = \frac{W(x(I)) - W(x(I-1))}{\Delta x} \quad (101)$$

Given this average heat release function, the integral along a characteristic can be performed. Note that reflection off the sidewalls must be included, as

can be seen in Figure 26. The contribution due to reflection at  $P_1$  is therefore found by finding the total heat released along the characteristic that reflects at  $P_2$ , then adding this to that found along  $P_2P_1$ .

(Note: For larger Mach angles ( $>\tan^{-1}(\Delta y/2\Delta x)$ ), the effective number of points in the direction is multiplied by a factor of KS in the program so that only information in two mesh rectangles is needed to find heat addition at the wall, i.e., extrapolation from the two nearest the sidewall, as can be seen from the following more detailed description of how the left and right characteristic terms are found.) Assume  $KS = 1$  and that the Mach angle is less than  $\tan^{-1}(\Delta y/2\Delta x)$ . This is assumed in the program by changing the total effective number of x coordinates to be  $KS \cdot NPTS$ .

Figure 26. Average heat release function.

Consider first the left characteristic term for the (I,J) point in Figure 27:

Figure 27. Left characteristic value.

The left characteristic value at (I,J) is that at P (found by a linear interpolation between the (I-1,J) and (I-1,J-1) points) plus the heat released in the region, again using a linear interpolation for H at (I-1,J) and (I-1,J-1).

Now consider a boundary point shown in Figure 28:

Figure 28. Boundary point.

To find the characteristic value at (I,1) it is necessary to know the value at point P which is in the (I,1) column on the sidewall. The value will then be a linear interpolation between the values at (I-1,1) and P plus a similar linear interpolation for the added heat.

To find the characteristic value at point P, the values at (I-2,2) and (I-2,1) are extrapolated linearly toward the boundary to find the value at point Q. Heat is then added, again by linear extrapolation.

Note that this detailed analysis at the boundary assumes that the characteristic of interest lies between the boundary at (I-1) and the (I-1,1) point, hence the necessity of the restriction that  $DYR = DYCH/DY$  be less than 0.5.

Analysis of the right characteristic is similar to that of the left characteristic.

The phase shift is found using the Gladstone-Dale relation.

$$n \approx 1 + C_D \quad (102)$$

The phase change  $\Delta\phi$  is

$$\Delta\phi = \frac{2\pi}{\lambda} \Delta n \Delta z = \frac{2\pi}{\lambda} \left( \frac{C}{\rho_0} \Delta\rho \right) \rho_0 \Delta z \quad (103)$$

This is then added to that of the unloaded density field to establish the total phase change at the gain/phase segment.

c. Fortran

Argument List

$$\Delta I C = \begin{cases} \text{wake for numerical kinetics} \\ \Delta I \times \frac{1}{\Delta Z} \left( \frac{1-n}{n} \right) \text{ for analytical kinetics} \end{cases}$$

DEN = phase change returned due to the FUHS effect

NCV - cavity number

## 12. SUBROUTINE GAINXY

a. Purpose -- GAINXY controls the gain calculations in the cavity. Figure 29 shows the Subroutine GAINXY flow chart. Either small signal gain (along one stream tube) or full-field-loaded gain is selected. From input cavity conditions (including vibrational temperatures of the constituents at

nozzle exit plane), all other thermodynamic parameters, energy levels, broadened line-width function, gain, optical cross section, and saturation intensity at a single point are given. Subroutine KINET is called to integrate the rate equations along the X-direction (streamtube). This is done only once for small signal gain. When loaded gain is selected the entire field is calculated and gain is updated by local intensity one step in the Z (propagation) direction. The loaded gain is hence a numerical (small step-wise integrated) process. This updated gain and intensity field is used to SOQ.

The single stream tube small signal gain is used in subroutine SIMPGG which computes a closed form solution of the full field loaded gain.

Subroutine MIX is called by subroutine GAINXY to calculate the transition rates.

A ratio technique is employed to effect calculation of the gain field for 9.27  $\mu$ lasing. This is triggered by GFACT = 1 for 10.60  $\mu$ ; GFACT = 1 for 9.27  $\mu$ .

b. Relevant formalism -- The option for small signal gain only or full-field loaded numerical gain is determined by IFIELD = 1 for small signal gain and IFIELD = 1 for numerical gain.

For small signal gain only, the gain is computed first at the nozzle exit plane and then computed along the flow direction by integrating the rate equations in subroutine KINET.

The particular initial thermodynamic conditions, rotational J values (P or R branch), and initial vibrational temperatures are brought in through common/CAV2/. Then, for a particular vibration-rotation transition, the gain coefficient is given by:

$$g_{v_j}^{v_j'} = \frac{8\pi^3}{3h} \left( \frac{M}{2\pi K T} \right)^{1/2} S_j F_j \left| R_{v_j, v_j'} \right|^2 \left[ \frac{n_{v_j}}{g_{v_j}} - \frac{n_{v_j'}}{g_{v_j'}} \right] \quad (104)$$

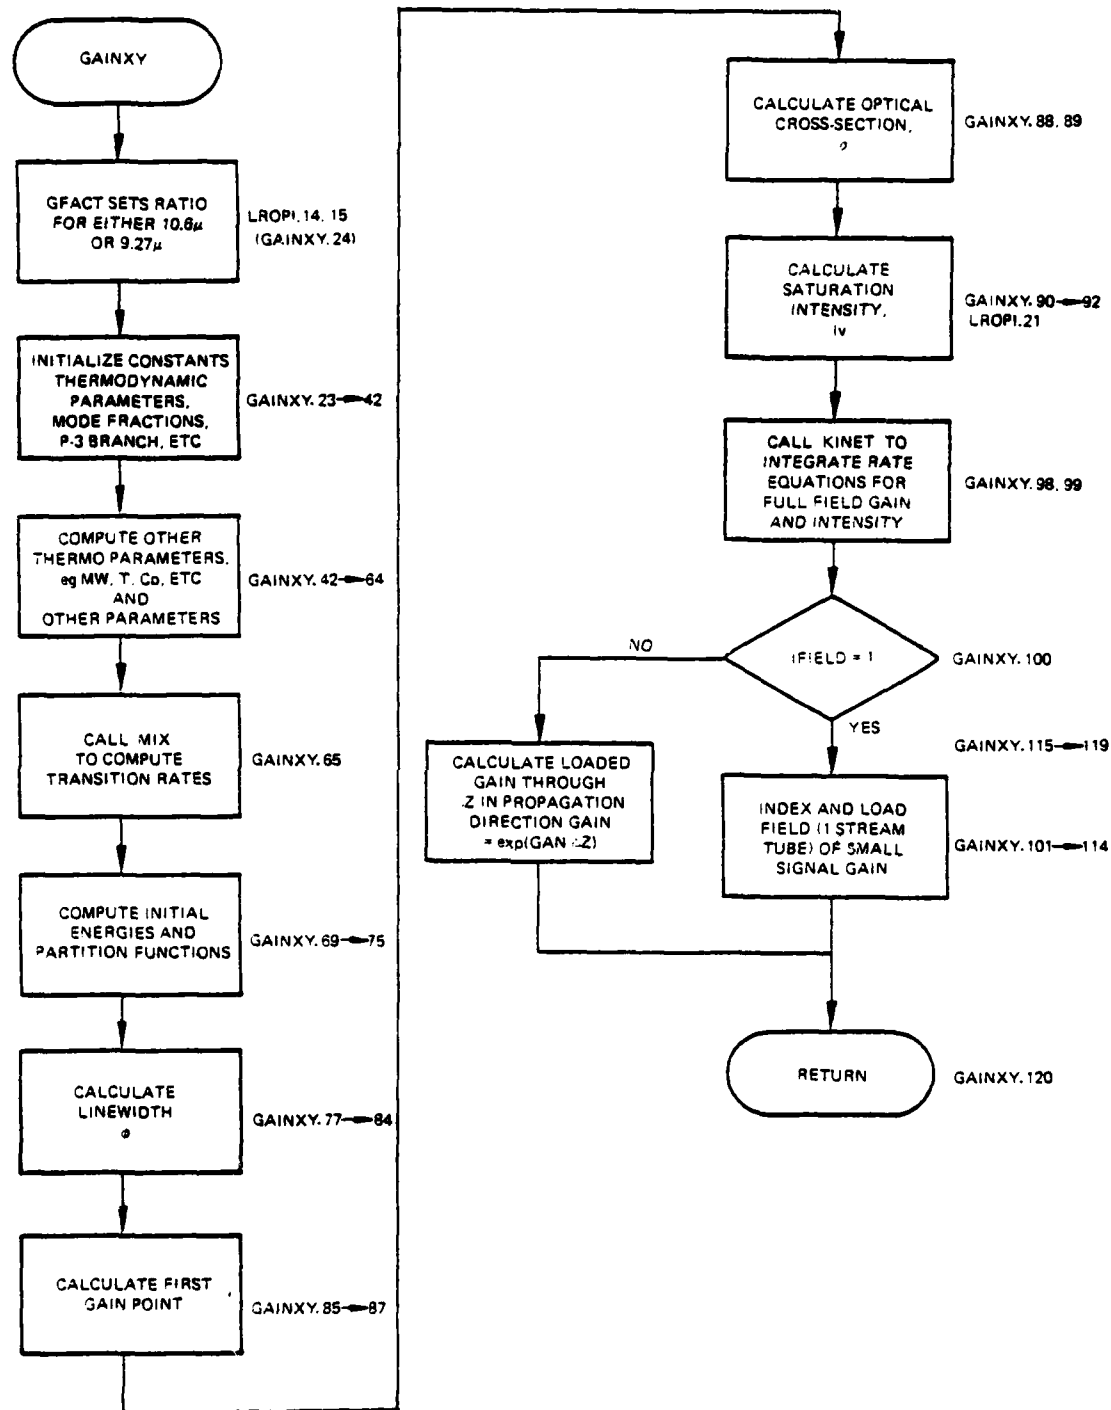

Figure 29. Subroutine GAINXY flow chart.

Where,

$$h = \text{Planck's constant} = 6.625 \times 10^{-27} \text{ erg}$$

$$M = \text{Mass of CO}_2 \text{ molecule} = 44 \times 1.66 \times 10^{-24} \text{ g}$$

$$K = \text{Boltzmann's constant} = 1.38 \times 10^{-16} \text{ erg/K}$$

$$S_J = \begin{matrix} J + 1 & \text{for } J' = J + 1 & (\text{P-branch}) \\ J & \text{for } J' = J - 1 & (\text{R-branch}) \end{matrix}$$

$$F_J = 1 + D_{v,v',m} \text{ where } M = - (J+1) \text{ P-branch}$$

$$M = J \text{ R-branch}$$

$R_{vv'}$  = Vibrational matrix element for transition

$\phi$  = lineshape factor

$$= e^{-\xi^2} \text{erfc}(\xi)$$

$$= (\ln 2)^{1/2} \alpha_p, \quad \alpha_p = \text{pressure-broadened half-width}$$

$$\alpha_d, \quad \alpha_d = \text{Doppler-broadened half-width}$$

$$\alpha_p = \frac{n}{2\pi c} \sum_{\text{SPECIES}} x_i \bar{v}_{i-\text{CO}_2} \bar{\sigma}_{i-\text{CO}_2}$$

$$\alpha_d = \frac{v_o}{c} \left( \frac{2KT \ln 2}{M} \right)^{1/2}$$

$n$  = total gas number density

$c$  = speed of light =  $3 \times 10^{10}$  cm/s

$x_i$  = mole fraction of the  $i$ th species

$\bar{v}_{i-\text{CO}_2}$  = mean velocity between  $\text{CO}_2$  and  $i$ th species

$M_{i-\text{CO}_2}$  = reduced mass of  $i-\text{CO}_2$  pair

$\alpha_{i-\text{CO}_2}$  = optical broadening cross-section

$v_o$  = frequency of transition  $(v, j) - (v', j')$

$$N_{VJ} = N_V f_J = N_V \frac{2J+1}{Q_{\text{rot}}^{(v)}} e^{-\frac{J(J+1)}{KT}} Q_{\text{rot}}^{(v)} \quad (105)$$

where,

$$Q_{\text{rot}}^{(v)} = \frac{T}{2\Theta_{\text{rot}}^{(v)}}$$

$$\frac{N_{VJ}}{g_{VJ}} = \frac{N_V}{g_V} \frac{\exp\left(-\frac{J(J+1)}{KT}\right)}{Q_{\text{rot}}^{(v)}}$$

$$\frac{N_V}{g_V} = N_{\text{ooo}} \exp(-\Theta_V/T_V)$$

$\Theta_V$  = Characteristic temperature of state

$T_V$  = Vibrational temperature of state

The saturation intensity is calculated:

$$I_{\text{SAT}} = \frac{h\nu\beta}{\sigma} \quad (106)$$

where,

$h\nu$  = photon energy

$\beta$  = lower laser level relaxation rate

$\sigma$  = optical cross-section of the transition

Where  $R_{c2}$  is the EOVO transition rate  $\sim (1/s)$ , all the initial energies of the vibration levels are computed before entering subroutine KINET.

$$EOOVI = \frac{X_{\text{co}_2} * 2349}{e^{\frac{hc * 2349}{KT_2}} - 1}$$

$$\begin{aligned}
 \text{EOVOI} &= \frac{X_{\text{CO}_2} * 2349}{\epsilon \frac{hc * 667}{KT_2}} - 1 \\
 \text{EVOOI} &= \frac{X_{\text{CO}_2} * 2349}{\epsilon \frac{hc * 1388}{KT_1}} - 1 \\
 \text{EN2I} &= \frac{X_{\text{N}_2} * 2331}{\frac{hc * 2331}{KT_{\text{N}_2}}} - 1
 \end{aligned}
 \tag{107}$$

Where  $X_{\text{CO}_2}$  and  $X_{\text{N}_2}$  are mole fractions of  $\text{CO}_2$  and  $\text{N}_2$ , and  $T_1$ ,  $T_2$ ,  $T_{\text{N}_2}$  are vibrational temperatures. These vibrational temperatures and levels are shown schematically in Figure 30.

Gain is computed as a function of  $x$  by calling "KINET."

When the loaded numerical gain option is triggered ( $\text{IFIELD} \neq 1$ ), the full field (in  $X$  and  $Y$ ) gain is calculated in KINET as a function of previous intensities and the field is updated when returned to GAINXY by propagating each local intensity through a  $\Delta Z$ , with local gain  $\text{GAN}(I)$ . The gain is thus recomputed for each point  $G(J) = e^{G(J) \cdot \Delta Z}$ .

### 13. SUBROUTINE GDL

a. Purpose -- Subroutine GDL is the main driver program for resonator and optical train calculations. It is here that the information about each resonator element is stored, as well as the order in which they are applied to the beam. Figure 31 shows the Subroutine GDL organization.

b. Formalism -- Subroutine GDL controls the iterative procedure of starting with a given field established in the main program (SOQ) and propagates this field through the resonator. Eventually, the mode which loses the least power (in the case of a bare resonator) or gains the most power (in the case of a loaded resonator) will predominate since the other modes will be suppressed due to relative power loss. For the degenerate case when two or more modes are competing for the status of lowest loss mode, the field will usually fail to converge to a single mode shape, since there is no unique mode for that eigenvalue.

c. Fortran -- To accomplish the above, GDL contains several fundamental arrays. One is the singly dimensioned CU array in which the field is stored. For a given point (x(I), x(J)) the field value is stored in the complex location.

CU (I + (J-1) \* NPTS)

Common /MELT/ contains CU as well as the work array CFIL, the coordinate array x, the location of the optical axis (DRX and DRY), and the iteration number NITER. This common is shared by most of the routines in the deck. The other major arrays are the ABC array, the IGDL array, and the GNOT array. During the first iteration of a particular run, GDL reads input from unit IN in the form of namelists and titles. The order of resonator elements to be met by the beam is controlled by the order in which the \$CONTRL cards are read. These contain the IFLOW parameters which designate specific elements, as follows:

NAMelist/CONTROL/IFLOW, SNOTE, IPLOTS

IFLOW CONTROLS THE FLOW OF CALCULATIONS THROUGH GDL

- = 1 CAVITY ELEMENT, READS CAVTY1, CAVTY2.  
(from CAVITY)
- = 2 MIRROR ELEMENT, READS MIRROR
- = 3 VAMP ELEMENT, READS PROPGT
- = 4 APERTURE ELEMENT, READS APTUR
- = 5 THERMAL BLOOMING, READS BLOOM
- = 6 INTERPOLATE FIELD OVER SMALLER AREA, READS CUTOUT
- = 7 TEST FOR CONVERGENCE OF ITERATION, NO INPUT
- = 8 PLOT FIELD DISTRIBUTION, READS TITLE
- = 9 RETURN CONTROL TO CALLING PROGRAM, NO INPUT
- = 10 READ AND/OR WRITE CU ON DISK, READS DISKIT
- = 11 AERO WINDOW R.M.S. PHASE MODEL, NO INPUT
- = 12 SCALING ROUTINE . . .MULTIPLIES ENTIRE FIELD,  
READS MULT
- = 13 FLIPS THE FIELD ABOUT THE y-AXIS, NO INPUT
- = 14 SINUSOIDAL DENSITY VARIATIONS, READS SINDEN
- = 15 REGRIDS FIELD TO LARGER SIZE, READS REGRID
- = 16 CU PUNCHED ON CARDS, NO INPUT
- = 17 MIRROR THERMAL BL MODEL, READS THRML
- = 18 SPIDER ROUTINE, READS SPIDR
- = 19 AXION ROUTINE, READS AXICON
- = 20 PROPAGATE IN R-THETA SPACE, READS RPROP
- = 21 REMOVES OR ADDS BACK BEAM CENTER, READS CENTER
- = 22 FLIPS THE BEAM ABOUT THE x-AXIS, NO INPUT

IPLOTS is the printer plot selector. IPLOTS=ABCDE, where A=1 selects R-theta plots, B=1 selects iso-intensity plot, C=1 selects x-axis plot, D=1 selects diagonal plot, and E=1 selects y-axis plot: example, IPLOTS = 1001 selects

iso-intensity and y-axis plots in x-y coordinates. The order of IFLOW numbers for a given resonator is then stored in the IGDL array for future iterations. In the same manner the associated titles are stored in the GNOT array.

Usually for a given IFLOW there is another associated namelist containing relevant element parameters. Once read in, these numbers are stored in ABC (I,J,K) where I indicates the parameter for the J the element of type K. The number (J) of the element is stored in common ZIP, which is equivalenced to the ICAVZ array. At the beginning of each iteration most of ICAVZ is filled with zeros so that the center index of the ABC array is correctly identified. At the end of each iteration, the current field is compared with that of the previous iteration in two ways: (1) the cutout and interpolated feedback field is compared and (2) the full field just before the hole-coupling mirror is compared. When the differences between two consecutive iterations fall within given tolerances (10% for the feedback field, 2% for the hole-coupler field and 0.7% for the power at the output of the resonator), the field is said to have converged, i.e., the lowest loss mode has been selected. A more detailed description of the meaning of each IFLOW, its function, and its associated namelist, if any, follows:

IFLOW = 1        (GDL. 422→GDL.446)

A GDL cavity is applied to the field. NEWCAV is calculated to see if the beam has been in the cavity before. The namelist used in CAVTY1.

CALLS CAVITY.

NAMLIST/CAVTY1/NCAVNO, ILR, NSTE, NPLT, ZPROP1, ZPROPO

NCAVNO IS THE NUMBER ASSIGNED TO CAVITY FOR IDENTIFICATION

ILR INDICATES DIRECTION OF FIELD THROUGH CAVITY

=    -1 RIGHT TO LEFT

=    +1 LEFT TO RIGHT

NSTE CONTROLS TYPE OF VAMP CODE BETWEEN SEGMENTS

=    1 CONSTANT MESH WITH SETUP

=    2 VARIABLE MESH WITH SETUP (EXITS VAMP AT END OF  
ELEMENT)

=    3 VARIABLE MESH WITH SETUP (REMAINS IN VAMP)

- = 4 USE EXISTING PROPAGATING MATRIX (EXITS VAMP)
- = 5 USE EXISTING PROPAGATING MATRIX (REMAINS IN VAMP)

NPLT CONTROLS INTERMEDIATE PRINTOUT FOR CAVITY

- = 0 NO PRINTOUT
- = 1 PRINT FIELD BEFORE AND AFTER GAIN, AND GAIN COEFFICIENT

ZPROPI IS PROPAGATION DISTANCE FROM PREVIOUS OPTICAL ELEMENT TO CAVITY.

ZPROPO IS PROPAGATION DISTANCE FROM CAVITY TO NEXT OPTICAL ELEMENT

IFLOW = 2 (GDL.527-GDL.558)

Here the parameters necessary for application of a mirror are set up.  
The namelist read is MIRROR. CALLS MIRROR

NAMelist/MIRROR/ANGXX, ANGY, RAD, DIAOUT, DIAIN, XMPOS, YMPOS, RMIR,  
X DELTA, DISTF, DDUTY, DINY, RANULS, PHIAT

ANGXX IS TILT IN x-DIRECTION - RADIANS (WRT OPT. AXIS)

ANGY IS TILT IN y-DIRECTION - RADIANS (WRT OPT. AXIS)

RAD IS RADIUS OF CURVATURE OF SPHERICAL MIRROR

DIAOUT IS OUTSIDE DIAMETER OF MIRROR

DIAIN IS INSIDE DIAMETER OF MIRROR

XMPOS IS X-DISPLACEMENT OF MIRROR FROM OPTICAL AXIS

YMPOS IS Y-DISPLACEMENT OF MIRROR FROM OPTICAL AXIS

RMIR IS REFLECTIVITY OF MIRROR

DELTA IS CENTER-TO-EDGE DISTORTION FACTOR (CM)

DISTF IS MIRROR DISTORTION FACTOR (DEFLECTION=DISTF\*I\*  
(1.0-RMIR))

RANULS IS OUTSIDE RADIUS OF ANNULAR BEAM (IF APPLICABLE)

DDUTY FLAGS THE TYPE OF APERTURE APPLIED -

.EQ. 0 - CIRCULAR APERTURE DEFINED AS ABOVE

.NE. 0 - RECTANGULAR APERTURE, DIAOUT HIGH (X) BY  
DDUTY WIDE (Y)

DINY IS SIMILAR TO DDUTY FOR INSIDE DIMENSIONS

PHIAST IS THE ANGLE OF INCIDENCE OF THE BEAM IN DEGREES

IFLOW = 3 (GDL.578→GDL.612)

For this IFLOW, a propagation step is applied. Relevant parameters are found in namelist PROPGT. CALLS STEP.

NAMelist/PROPGT/DELZ, RDCURV, WINDOX, WINDOK, IIFG, IITR, IIPS

DELZ IS PROPAGATION DISTANCE

RDCURV IS RADIUS OF CURVATURE OF PHASE FRONT

IF (ABS (RDCURV) .LT.0.5) USE RADCUR OF PREVIOUS

MIRROR

WINDOX IS X-SPACE DATA WINDOW FOR FFT

WINDOK IS K-SPACE DATA WINDOW FOR FFT

IIFG IS A VAMP CONTROL PARAMETER

= 1 FOR CONSTANT MESH

= 2 FOR VARIABLE MESH

IITR IS ANOTHER VAMP CONTROL PARAMETER

= 0 NO INVERSE TRANSFORM

= 1 INVERSE TRANSFORM BACK TO REAL SPACE

IIPS IS FOR CORRECTION OF PLANE AND SPHERICAL PHASE

FRONTS

= 0 NO CORRECTION

= 1 PLANAR CORRECTION ONLY

= 2 QUADRATIC CORRECTION ONLY (NOT OPERATIONAL)

= 3 BOTH

IFLOW = 4 (GDL.613→GDL.631)

Here an aperture is applied. IF DOUT and DIN are both less than 0, SLIVER is called. If both are greater than or equal to zero, APRTR is called. The relevant namelist is APTUR.

AD-A103 285

UNITED TECHNOLOGIES CORP WEST PALM BEACH FLA

AFWL-TR-79-141-PT-2

NL

2 of 3

AD-A103 285

1-13-75

NAMelist/APTUR/DOUT, DIN, XPOS, YPOS, YOUT, YIN

DOUT IS OUTSIDE DIAMETER OF APERTURE

DIN IS INSIDE DIAMETER OF APERTURE

XPOS IS x-DISPLACEMENT OF APERTURE FROM OPTICAL AXIS

YPOS IS y-DISPLACEMENT OF APERTURE FROM OPTICAL AXIS

YOUT FLAGS THE TYPE OF APERTURE APPLIED -

.EQ.0 - CIRCULAR APERTURE DEFINED AS ABOVE

.NE.0 - RECTANGULAR APERTURE, DOUT HIGH (X) BY  
YOUT WIDE (Y)

YIN IS SIMILAR TO YOUT FOR INSIDE DIMENSIONS

IFLOW = 5 (GDL.632-GDL.652)

Thermal Blooming is applied to the complex field. BLOOM is read in and subroutine TBLCOM is called.

NAMelist/BLOOM/ALFA, SCP, T, RHO, ZLEN, NSTEPS, INPT, NPROP, AXIAL, DT

AFLA = MEDIUM ABSORPTION COEFFICIENT,  $\text{CM}^{-1}$   
SCP = MEDIUM SPECIFIC HEAT, J/GM-DEG K  
T = MEDIUM TEMPERATURE, DEG K  
RHO = MEDIUM DENSITY, GM/CM<sup>3</sup> (OR TRANSVERSE VEL.  
IF .GT.1.)  
ZLEN = MEDIUM THICKNESS ALONG OPTICAL AXIS  
NPROP = PROPAGATION PARAMETER. . .SAME AS NSTE IN  
CAVITY  
NSTEPS = NUMBER OF ELEMENTS IN SUBSYSTEM, .GE. 1  
INPT = .NE.0 FOR INTERMEDIATE FIELD PLOTS  
AXIAL = AXIAL VELOCITY (CM/SEC) IF .GT. 0, USES  
AXIAL BLOOMING  
DT = BEAM ON TIME FOR THERMAL BOUNDARY LAYER  
GROWTH IN TRANSIENT BLOOMING CALCS. IF  
DT.GT.0 USES TRANSIENT BLOOMING

IFLOW = 6 (GDL.653-GDL.779)

For this option the field can be cut out and interpolated from one region size to another. The number of points is not changed. If CUSMF is not equal to zero, the field-averaged feedback field is stored on unit 8 and the convergence checks are made on the feedback field and the pre-HCM field which is stored on unit 7 temporarily. The field for the bare-resonator is renormalized at this point to unit maximum intensity. Namelist CUTOUT has the information for the new region in it as well as other parameters.

NAMelist/CUTOUT/DIBeam, OVRlap, DXxR, DYyR, MAXIT, AVCUSM, CUSMF

CUSMF = 1. FOR NORMAL LOADED RESONATOR CUTOUT

CUSMF = 0. AVOIDS WRITING FIELD ON 8 AND AVOIDS NORMALIZ-  
ING FIELD, CHANGES TO THE NEW COORDINATES,  
THEN RETURNS.

DIBeam IS THE DIAMETER OF BEAM FOR NEXT ITERATION

OVRLAP IS DCALC = OVRLAP\*DIBeam

DXxR IS POSITION OF ITERATIVE BEAM REL. TO OPTICAL AXIS

DYyR IS THE SAME

MAXIT IS THE MAXIMUM NUMBER OF ITERATIONS

AVCUSM AVERAGES PREVIOUS AND NEXT ITERATION GUESS IN THE

HOPE OF RAPID CONVERGENCE...=0 NO AVE, = .5 HALF AND HALF

IFLOW = 7 (GDL.795→GDL.842)

There is no namelist associated with this option. The convergence check on the power is made here. If the solution has not yet converged, the gain/phase information is updated by a call to REGAIN, then the resonator is restarted for the next pass.

IFLOW = 8 (GDL.500→GDL.513)

If the parameter plot is non-zero in namelist START in SOQ, this IFLOW will generate printer plots by a call to IPLOT. Namelist PLOT is read.

NAMelist/PLOT/TITLE RADPLT

TITLE IDENTIFIES THE POSITION OF EACH STATION PLOTTED

RADPLT CONTROLS THE TYPE OF PLOT

= 0.0 FOR X,Y PLOTTING (X-AXIS, Y-AXIS, DIAGONAL)

= 1.0 FOR RADIAL PLOTTING AT VARIOUS THETAS

IFLOW = 9

This IFLOW only results in the return to the main program, SOQ.

IFLOW = 10 (GDL.447→GDL.475)

This option allows the field to be read in from or read to a specific unit in standard SOQ format. It calls no peripheral subroutines and reads the unit designation from namelist DISKIT.

NAMelist/DISKIT/IREAD, IWRITE, IORD, IADD

IREAD IS THE DISK # TO BE READ OFF/ON... IF=0...DON'T

READ

IWRITE IS THE DISK # TO BE WRITTEN ON... =0...DON'T WRITE

IORD IS THE ORDER = 1, READ FIRST  
=-1, WRITE FIRST

IADD = 1 UPDATES IWRITE BY 1 FOR SUCCESSIVE ITERATIONS

IFLOW = 11 (GDL.476→GDL.482)

This option applies an aerodynamic window to the complex field. It reads no namelist and calls AEROW to perform the calculation.

IFLOW = 12 (GDL.483→GDL.499)

The field can be scaled using this option. At the same time the x array can also be magnified. No subroutines are called and MULT is read.

NAMelist/MULT/TRANS, XMAG

TRANS IS TRANSMISSION OF ELEMENT

XMAG IS MAGNIFICATION FACTOR FOR THE X-ARRAY

IFLOW = 13 (GDL.514→GDL.526)

This option flips the field about its y-axis. No namelists are read and no subroutine called.

IFLOW = 14 (GDL.408→GDL.421)

This option imposes a sinusoidal density (phase) variation to the existing complex field. It calls no subroutines, but it reads SINDEN for information on the sine wave.

NAMelist/SINDEN/NBEAM, AWL

NBEAM IS THE NUMBER OF CYCLES PER X-CALCULATED REGION

AWL IS THE AMP/WL OF THE SINUSOIDAL VARIATIONS

IFLOW = 15 (GDL.780-GDL.793)

The field can have superimposed on it a different number of mesh points. The spacing between two adjacent points does not change unless RGRD is called. Just the number of points in the mesh changes. If the number of points is increased, RGRD adds zeros to the outside of the existing region. This option reads namelist REGRID

NAMelist/REGRID/NGRD

NGRD IS NO. OF FIELD POINTS ACROSS REGRIDDED DCAL

IFLOW = 16 (GDL.390-GDL.406)

In this IFLOW, no subroutine is called and no input is read. The field and coordinates are written format to TAPE 4 in cards to be punched.

IFLOW = 17 (GDL.559-GDL.557)

Quiescent thermal gradients are imposed by this option. Namelist THRML is read and subroutine THERML is called.

NAMelist/THRML/ALPHAM, CONMIR, ALPHAG, RHOGAS, TAU, TIN, REFMIR, CONGAS

THRML IS THE NAMelist FOR BOUNDARY LAYER THERMAL LENS  
CALCULATIONS

ALPHAM = MIRROR DIFFUSIVITY (CM<sup>2</sup>/SEC)

CONMIR = MIRROR THERMAL CONDUCTIVITY (WATTS/CM-SEC)

ALPHAG = THERMAL DIFFUSIVITY OF GAS HEATED BY MIRROR  
(CM<sup>2</sup>/SEC)

CONGAS     = THERMAL CONDUCTIVITY OF GAS HEATED BY MIRROR  
                  (WATT/CM-SEC)  
 RHOGAS     = DENSITY OF GAS HEATED BY MIRROR (GM/CC)  
 TAU         = BEAM ON TIME FOR BOUNDARY LAYER GROWTH (SEC)  
 TIN         = INITIAL TEMPERATURE OF GAS & MIRROR (DEG K)  
 REFMIR     = MIRROR REFLECTIVITY (OBTAINED FROM MIRROR  
                  INPUT)

THERMAL MAY BE APPLIED AFTER ANY MIRROR TO ALTER THE GAIN-  
 PHASE DUE TO HEATING OF THE QUIESCENT BOUNDARY LAYER  
 ADJACENT TO THE MIRROR SURFACE.

IFLOW = 18                    (GDL.378-GDL.389)

With IFLOW = 18, a spider obscuration can be applied. Subroutine SPIDER  
 is called using the information read in with namelist SPIDR.

NAMelist/SPIDR/NSPD, WIDTH, THETA, XSPC, YSPC, DIH

NSPD         = NUMBER OF STRUTS IN SPIDER (MAX=6)  
 WIDTH         = WIDTH OF SPOKES IN SPIDER  
 THETA         = ANGLE OF INDIVIDUAL SPOKES OF SPIDER  
 XSPC         = x-LOCATION OF CENTER OF SPIDER  
 YSPC         = y-LOCATION OF CENTER OF SPIDER  
 DIH           = HUB DIAMETER

IFLOW = 19                    (GDL.366-GDL.377)

This option allows for the application of an axicon. Subroutine AXICV  
 is called after namelist AXICON is read.

NAMelist/AXICON/CAPR, EXPAND, ROC, DISP, TILT

CAPR IS THE OUTSIDE RADIUS OF THE ANNULAR EXTRACTION BEAM.  
 (EXPAND.EQ. .TRUE.) MEANS THE BEAM IS GOING FROM CIRCULAR  
 TO ANNULAR IN CROSS-SECTION  
 ROC           = RADIUS OF CURVATURE OF THE FIELD IN PHYSICAL  
                  SPACE

DISP       = DISPLACEMENT OF AXICON FROM CENTER ALONG  
           X-AXIS

TILT       = ANGLE (RADIAN) OF AXICON TILT FROM DIRECTION  
           OF PROP.

IFLOW = 20               (GDL.347-GDL.365)

This option propagates an unrolled annulus. After reading in namelist RPROP, it then calls subroutines RSTEP to perform the propagation and POWR to determine the power after propagation.

NAMelist/RPROP/DELZR, DELZTH, WINDOW, WINDOK

DELZTH IS PROPAGATION DISTANCE FOR THE RADIAL COORDINATE  
DELZTH IS PROPAGATION DISTANCE FOR THE ANGULAR COORDINATE

\*\*\* (DELZR .NE. DELZTH) MEANS YOU ARE MAKING AN  
EQUIVALENT COLLIMATED BEAM PROPAGATION STEP  
IN R-THETA COORDINATES\*\*\*

WINDOW IS X-SPACE DATA WINDOW FOR FIT

WINDOK IS K-SPACE DATA WINDOW FOR FFT

IFLOW = 21               (GDL.329-GDL.346)

This option allows for the removal of the center of the beam which is then stored on unit 20, or it can allow for the addition of a field read from unit 20 modified by a phase change. This work is all done in subroutine FIELDS using the information read in from namelist CENTER

NAMelist/CENTER/DSM, REMOVE, PHIARB

DSM IS THE DIAMETER TO BE REMOVED AND LATER ADDED TO THE  
MAIN BEAM

REMOVE FLAGS THE ACTION

.TRUE. IF THE CENTER PORTION OF THE BEAM IS TO BE REMOVED

.FALSE. IF THE REMOVED PORTION IS TO BE ADDED BACK TO THE  
BEAM

PHIARB IS AN ARBITRARY PHASE CHANGE ADDED TO THE CENTRAL  
PORTION

IFLOW = 22 (SQ77CY1.169+SQ77CY1.181)

This option flips the field about the x-axis. No input is required and no subroutines are called.

#### Argument List

IN - INPUT UNIT FOR RESONATOR DATA

RESTRT - NEW OR OLD RESONATOR?

ABC - PARAMETER ARRAY

NITER - CURRENT ITERATION

IB - INPUT UNIT # OF OLD FIELD

IFLAG == 1 TRANSFERS TO OLD ENTRY POINT - READS FIELD FROM IB/  
CONTINUES.

ABC and NITER can be redefined by this subroutine.

#### Common Variables Modified:

The common variable not modified by GDL are:

WL, NPTS, NPY, RADCUR, WNOW and NREG. Note that NBC is modified by its equivalence with IGDL and IDIR.

SUBROUTINE GDL 76/176 OPT=1 FIN 4.6+452 04/27/79 12.23.47

#### 14. SUBROUTINE INTERP

a. Purpose -- Subroutine INTERP performs linear interpolation on two-dimensional real functions and on the real and imaginary parts of two-dimensional complex functions. Figure 32 describes the subroutine INTERP organization.

b. Relevant formalism -- Consider first the one-dimensional case in Figure 33. Assume the function value  $f$  is desired at a point  $x^*$ , between points  $x_1$  and  $x_2$ , with associated function values  $f_1$  and  $f_2$ , respectively:

Linear interpolation between  $f_1$  and  $f_2$  yields  $f$  as

$$f(x^*) \approx f_1 + \frac{(x - x_1)}{(x_2 - x_1)} (f_2 - f_1) \quad (108)$$

where the  $\approx$  is used since we are approximating  $f$  over the subinterval  $(x_1, x_2)$ .

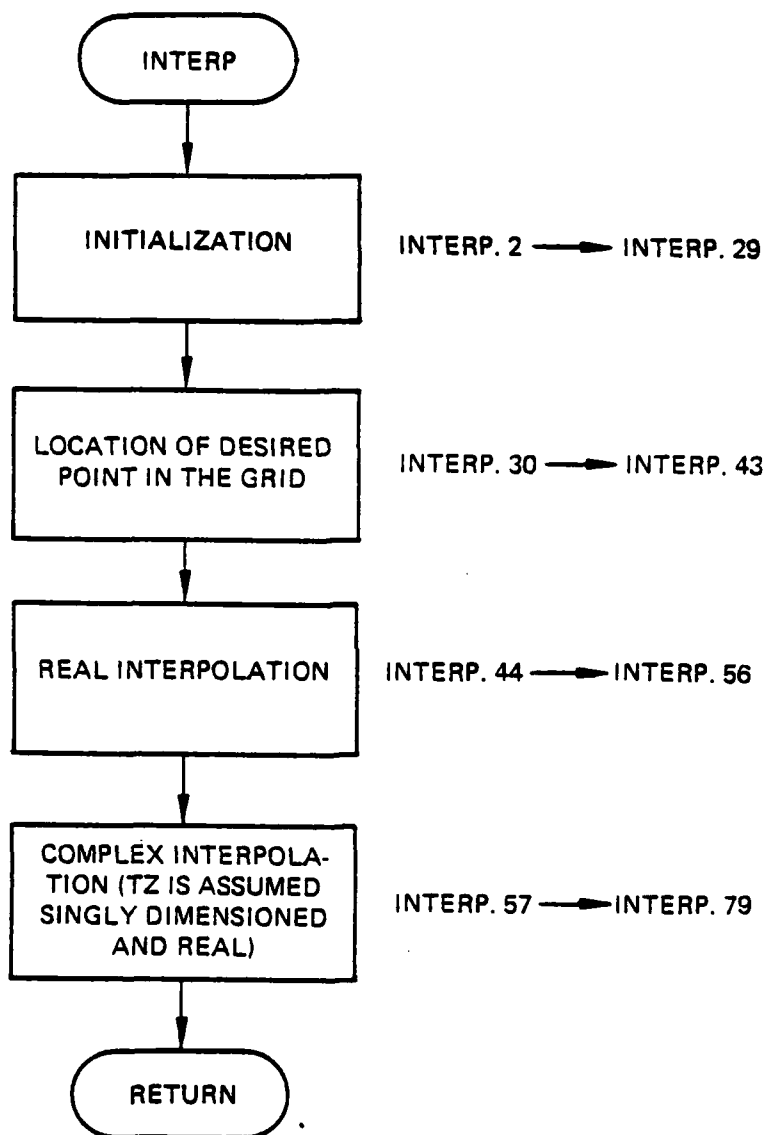

Figure 32. Subroutine INTERP organization.

Figure 33. One-dimensional function case.

For the two dimensional case in Figure 34, subroutine INTERP establishes the location of the far corners of the rectangle bounding the desired point  $(x, y)$ , then linearly interpolates across top and bottom to find the two values at  $x$ . It then interpolates between these two points to find the value at  $(x, y)$ :

Figure 34. Two-dimensional function case.

$$f(x, y_2) \approx f_{\text{TOP}} = f_3 + \frac{(x - x_1)}{(x_2 - x_1)} (f_4 - f_3) \quad (110)$$

$$f(x, y_1) \approx f_{\text{BOTTOM}} = f_1 + \frac{(x - x_1)}{(x_2 - x_1)} (f_2 - f_1)$$

$$f(x,y) = f_{\text{BOTTOM}} + \left[ \frac{(y - y_1)}{(y_2 - y_1)} \right] * (f_{\text{TOP}} - f_{\text{BOTTOM}})$$

c. Fortran

Arguments:

TXY = an array containing coordinate information  
 (XIN, YIN) = the point at which the function value is desired  
 TZ = the function to be interpolated  
 TYPE = 1 real  
 = 2 complex

ZZ = two element array containing the interpolated value.

Note: If TZ is real, ZZ must still be dimensioned to 2 in the calling program, then the first element used as the answer.

NSYM = 1 symmetric,  
 = 0 nonsymmetric

Note: Interpolation outside the region of definition of the distribution returns (0.0, 0.0) as the value of the interpolate.

There are no commons and no other subroutines are called.

Computer printouts of subroutine INTERP follow.

## 15. SUBROUTINE IPLOT

a. Purpose -- Subroutine IPLOT has two major purposes: One is to create a printer iso-intensity plot. The other is to find the maximum intensity and to print the first title used by subroutine OUTPUT. It also contains the necessary information used by both subroutines OUTPUT and OUTPUR to determine whether a particular slice plot should be printed. Figure 35 describes the subroutine IPLOT organization.

b. Relevant formalism -- The output of this subroutine is an array of one-digit adjacent members with at least one asterisk, which indicates the maximum intensity points. The numbers indicate relative intensities.

c. Fortran

### Argument List

The only argument of subroutine IPLOT is the parameter IPLTS which contains the information needed by OUTPUT (and OUTPUR) as well as IPLOT. IPLTS is filled with zero to five digits, each of which is 0 or 1. If it is 0, the indicated plot is not done; if 1, it is plotted. Assuming that the five digits of IPLTS are written ABCDE, the associated plots are:

- A: Radial (calls OUTPUR - not available)
- B: Iso-intensity
- C: X-axis slice plot
- D: Diagonal slice plot
- E: y-axis slice plot

### Common Parameters:

The only common modified is CFIL due to its equivalence with US, the intensity array. The other parameters have then usual meaning including PLOTSG.

Recall: PLOTSG > 0 → intensity slice plots  
          = 0 → no plots  
          < 0 → amplitude slice plots

Subroutines called: OUTPUT, OUTPUR

Computer printout of subroutine IPLOT follows.

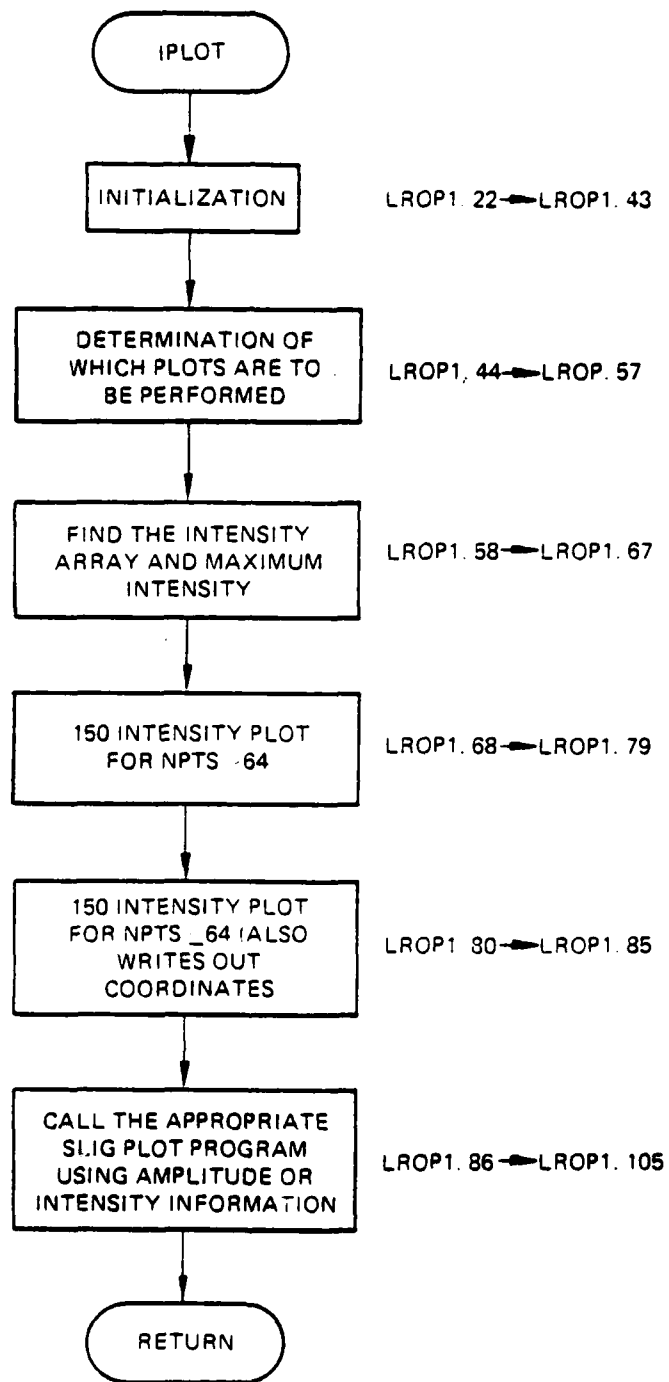

Figure 35. Subroutine IPLOT organization.

#### 16. SUBROUTINE KINET

a. Purpose -- This subroutine calculates the kinetics and loaded gain in the gas dynamic laser cavity. It is called by GAINXY for either small signal gain calculation (along a single stream tube in the x-direction) or full field loaded gain along several stream tubes. Figure 36 describes the subroutine KINET flow chart.

An intensity field VIC and previous gain field GAN are brought in from GAINXY and are updated by recomputing the kinetics and gain in the cavity as a function of these updated fields. The population rate equations (i.e., the equations showing the rate at which the energy of each vibrational level is changing) are numerically integrated along the x(flow)-direction. This is continued along the x-direction until the end of the calculation region (IXMAX) and is then redone for each stream tube in the y-direction (if full loaded gain is requested by IFIELD  $\neq$  1). The full gain field GAN (I) is then updated.

The assumption is made that the flow area of the cavity is constant through the region of interest for all kinetics calculations.

b. Relevant formalism -- Gain is calculated in the x-direction from nozzle exit plane to the end of the region of interest IXMAX at a constant y value, as shown in Figure 37. This is done along only one mid-cavity stream tube for small signal gain calculation and at every y-value (IY) for the full field loaded gain calculations.

Figure 37. Region of interest IXMAX.

Rate equations are set up for each level which describe the energy in that level.

$$\frac{dE}{dt} \text{ upper} = \left[ \frac{dE}{dt} \right]_{V-T} + \left[ \frac{dE}{dt} \right]_{V-V} + \left[ \frac{dE}{dt} \right]_{S.E.} \quad (111)$$

$$\frac{dE}{dt} \text{ lower} = \left[ \frac{dE}{dt} \right]_{V-T} + \left[ \frac{dE}{dt} \right]_{V-V} + \left[ \frac{dE}{dt} \right]_{S.E.} \quad (112)$$

$$\frac{dE}{dt} N_2 = \left[ \frac{dE}{dt} \right]_{V-T} + \left[ \frac{dE}{dt} \right]_{V-V} \quad (113)$$

The energies of each level EN2, EOOV, EVOO and EOVO are updated at each  $\Delta X$  step, i.e., the  $\Delta E$  change is computed and the corresponding heat addition (local temperature change) is used to compute the energy in the subsequent step.

The stimulated emission energy rate can be used to determine local intensity change and, hence, gain. Energies of levels are described by population densities  $n_u$  and  $n_L$ :

$$\frac{dI_\nu}{ds} \Big|_{u \neq L} = h\nu \left\{ n_u \bar{N}_{UL}(\nu) A_{UL}(\nu) - \left[ n_L \phi_{LU}(\nu) B_{LU} - n_u N_{UL}(\nu) B_{LU} \right] I_\nu \right\} \quad (114)$$

where  $I_\nu$  is the specific intensity at the frequency  $\nu$ ;  $n_U$  is the population density of the upper level;  $n_L$ , that of the lower level;  $A_{UL}$  the Einstein coefficient for spontaneous emission;  $B_{UL}$ , the stimulated emission coefficient; and  $B_{LU}$ , for absorption. The quantities  $\eta_{UL}$ ,  $N_{UL}$  and  $\phi_{LU}$  are the line shape functions for the three respective processes, which are generally different.

Characteristic times for the spontaneous decay of low-lying vibrational states for molecular species of interest are of the order  $10^{-1}$  to  $10^{-5}$  second, whereas other rate processes are typically much faster. Hence, in the equation above, the spontaneous emission term generally can be neglected. Also, for the present analyses, interest focuses primarily on photon processes occurring at line center. At line center  $\phi_{LU} = \eta_{UL}$ . Thus,

$$\frac{dI_\nu}{ds} = h\nu\phi_{LU}(\nu_\sigma) \left[ B_{UL} n_u - B_{LU} n_L \right] I_{\nu_0} \quad (115)$$

The factor multiplying  $I_{\nu_0}$  is the optical gain coefficient, viz:

$$g_{UL} = h\nu\phi_{LU} \left[ B_{UL} n_u - B_{LU} n_L \right] \quad (116)$$

The Einstein coefficients are connected by the relationship

$$\frac{B_{LU}}{B_{UL}} = \frac{d_u}{d_L} \quad (117)$$

where  $d_U$  and  $d_L$  are degeneracies (statistical weights) of the upper and lower states, respectively. Also, it is possible to write

$$B_{LU} = \frac{8\pi^3}{3h^2c} \left| R_{LU} \right|^2 \quad (118)$$

where  $R_{LU}$  is the quantum-mechanically-derived transition matrix element. Hence, the gain expression may be rewritten as

$$g_{UL} = \frac{8\pi^3}{3h} \left( \frac{\nu_0}{c} \right) \phi_{LU}(\nu_0) \left| R_{LU} \right|^2 \left[ \frac{n_u}{d_u} - \frac{n_L}{d_L} \right] \quad (119)$$

or

$$g_{vj}^{j'} = \frac{8\pi^3}{3h} \frac{\nu_0}{c} \phi_{LU} \nu_0 \left| R_{LU} \right|^2 \left[ \frac{n_{vj}}{d_{vj}} - \frac{n_{vj'}}{d_{vj'}} \right] \quad (120)$$

Consider vibrational-rotational transitions of the form

$$(v+1, J) \leftrightarrow (v, J)$$

where  $v$  is the vibrational quantum number and  $J$  is the rotational quantum number.

Then

$$\left| R_{LU} \right|^2 = S_J \left| R_{v, v+1} \right|^2 \quad (121)$$

where:

$$S_J = \begin{cases} J & \text{for P-branch transitions (i.e., } J' = J + 1) \\ J + 1 & \text{for R-branch transitions (i.e., } J' = J - 1) \end{cases}$$

$$R_{v, v+1} = \text{vibrational-transition matrix element}$$

At pressures of a few torr or less, transitions are predominately Doppler broadened. At higher pressures, the combined influence of Doppler and pressure (Lorentz) broadening is present. Therefore, the line-shape factor  $\phi_{LU}(\nu_0)$  is represented in terms of a Voigt profile such that

$$\frac{v_0}{c} \phi_{Lu}(v_0) = \left( \frac{m}{2\pi KT} \right)^{1/2} \exp(\xi)^2 \operatorname{erfc}(\xi) = \left( \frac{m}{2\pi KT} \right)^{1/2} \phi(\xi) \quad (122)$$

$$a_D(v_0) = \left( \frac{K}{n} \right) \left( \theta_{001} - \theta_{001} + J(J+1) \theta_{\text{rot}}^{001} - J'(J'+1) \theta_{\text{rot}}^{100} \right) \quad (123)$$

$(\theta_{02^0 0})$ 
 $(\theta_{\text{rot}}^{020})$

$$a_{\text{CO}_2 - \text{CO}_2} = \frac{001 \rightarrow 100}{10.5 \times 10^{-15} \text{ cm}^2} \quad (124)$$

$$a_{\text{CO}_2 - \text{CO}_2} = \frac{001 \rightarrow 02^0 0}{10.2 \times 10^{-15} \text{ cm}^2} \quad (125)$$

The influences of Doppler broadening and vibration-rotation interaction have been taken into account.

where

$$\xi = \frac{a_p}{a_D} \sqrt{\ln 2} \quad (126)$$

$a_p$  = pressure broadened (Lorentz) half-width

$$= \frac{n}{2\pi c} \sum_s v_s X_s \sigma_s$$

$a_D$  = Doppler broadened half-width

$$= \frac{v_0}{c^2} \sqrt{\frac{2kT(\ln 2)}{m}}$$

$v_s$  is the mean relative velocity ( $\sqrt{2kT/M}$ ) between the emitting molecule and the colliding species;  $X_s$  is the species mole fraction,  $\sigma_s$  is the broadening cross-section due to the impacting species  $s$ ;  $v_0$  is the transition frequency at line center;  $m$  is the mass of the emitter molecule; and  $M$  is the reduced mass between an emitter molecule and the collider molecule of species  $s$ :

$$\mu = \frac{m m_s}{m + m_s} \quad (127)$$

The optical gain coefficient may be rewritten as

$$g(V, J) = \frac{8\pi^3}{3h} \left( \frac{m}{2\pi kT} \right)^{1/2} \phi(\xi) S_J \left| R_{V, V+1} \right|^2 \left[ \frac{n_{V+1, J'}}{d_J} - \frac{n_{V, J}}{d_J} \right] \quad (128)$$

Here the quantities  $V$  and  $J$  in the expression  $g(V, J)$  indicate the lower levels of the transition.

In treating the populations of the vibrational-rotational levels, it is assumed that the rotational mode can be described by the local translational temperature  $T$ . Hence,

$$n_{V, J} = \left( \frac{n_{V, J}}{n_V} \right) n_V = \frac{d_J \exp \left[ -1.439 J(J+1) (B_e - \alpha_e (v+1/2)/T) \right] n_V}{Q_{\text{rot}}(V)} \quad (129)$$

where  $B_e$  is the spectroscopic rotational constant ( $\text{cm}^{-1}$ ), and  $\alpha_e$  is its anharmonic correction. The quantity  $Q_{\text{rot}}^{(V)}$  is the rotational partition function, which is evaluated according to the relation

$$Q_{\text{rot}}(V) = \sum_J (2J+1) \exp (-E_{\text{rot}}(J, V)/kT) \quad (130)$$

The populations can also be represented by:

$$n_{VJ} = n_V f_J = n_V \left[ \frac{2J+1}{Q_{\text{rot}}^{(V)}} \right] \exp \left( \frac{-J(J+1)}{kT} \alpha_e^{(V)} \right) \quad (131)$$

where,

$$Q_{\text{rot}}^{(V)} = \frac{T}{2\theta_{\text{rot}}^{(V)}}$$

$$\frac{n_{VJ}}{g_{VJ}} = \frac{n_V}{g_V} \exp\left(\frac{-J(J+1)}{kT}\right) \theta_{\text{rot}}^{(V)}$$

$$\frac{n_V}{g_V} = n_{000} \exp(-\theta_V/T_V)$$

$\theta_V$  = characteristic temp. of state

$T_V$  = vibrational temperature of state

$g_V, g_{VS}$  represent degeneracies

For the transitions

the pertinent constants are:

$$R_{001,100} = 0.0331 \times 10^{-18} \text{ esu-cm}$$

$$R_{001,02^0 0} = 0.0295 \times 10^{-18} \text{ esu-cm}$$

$$\theta_{\text{rot}}^{(001)} = 0.55632 \text{ K}$$

$$\theta_{\text{rot}}^{(02^0 0)} = 0.56106 \text{ K}$$

$$\theta_{\text{rot}}^{(100)} = 0.56078 \text{ K}$$

$$\theta_{001} = 3380 \text{ K} \quad \theta_{100} = 1997 \text{ K}$$

$$\theta_{020} = 1850 \text{ K}$$

The expressions for the gain coefficients on two transitions are

$$g_{001,J}^{700,J} = (0.79 \times 10^{-14}) |m| (1 - 0.0044m) T^{-\frac{3}{2}} n X_{000} \phi \left[ (0.55632) \exp \left( \frac{-3380}{T_{001}} - J(J+1) (0.55632/T) \right) - (0.56078) \exp \left( \frac{-2000}{T_{100}} - J'(J'+1) (0.56078/T) \right) \right] \quad (132)$$

$$g_{001,J}^{020,J'} = (0.63 \times 10^{-14}) |m| (1 - 0.006m) T^{-\frac{3}{2}} n X_{000} \phi \left[ (0.55632) \exp \left( \frac{-3380}{T_{001}} - J(J+1) (0.55632/T) \right) - (0.56106) \exp \left( \frac{-1850}{T_{020}} - J'(J'+1) (0.56106/T) \right) \right] \quad (133)$$

where  $m = -(j + 1)$   $J' = J + 1$  (P)

$m = J$   $J' = J - 1$  (R)

$n = \text{total number density} = \frac{p}{KT}$

$X_{000} = \text{mole fraction of ground state CO}_2 \text{ (from program)}$

$J' = 0, 2, 4, 6, \dots$

For largely pressure-broadened line,  $\phi$  may be expressed as:

$$\phi \approx \frac{1}{\sqrt{\pi} \xi} \left[ 1 - \frac{0.5}{\xi^2} + \frac{0.75}{\xi^4} - \frac{1.875}{\xi^6} + \frac{6.5625}{\xi^8} - \dots \right] \quad (134)$$

#### Argument List

XIC	The field (matrix) of individual intensities in the calculation region
GAN	Gain (updated) of each of the point locations of the field
IXMAX	Number of points in the flow direction

DXCAV The distance between points in the x-direction  
 IFIELD Indicator for small signal gain (IFIELD = 1) or Loaded Gain (IFIELD  $\neq$  1)  
 IY Number of flow streams, i.e., points in the y-dimension.

# Commons Modified

## 17. SUBROUTINE MIRROR

a. Purpose -- MIRROR applies a mirror transmission function to the complex field which may include reflectivity, clipping, radius of curvature, edge diffraction imaging, small tilt, astigmatism, localized surface distortion, and overall spherical distortion. In addition, two specialized options have been included: (1) a toric mirror effect for axicon optics and (2) a mirror dimple effect which enables a localized difference in radius of curvature. Figure 38 shows the subroutine MIRROR organization. Computer printouts of the MIRROR subroutine begin on page 168.

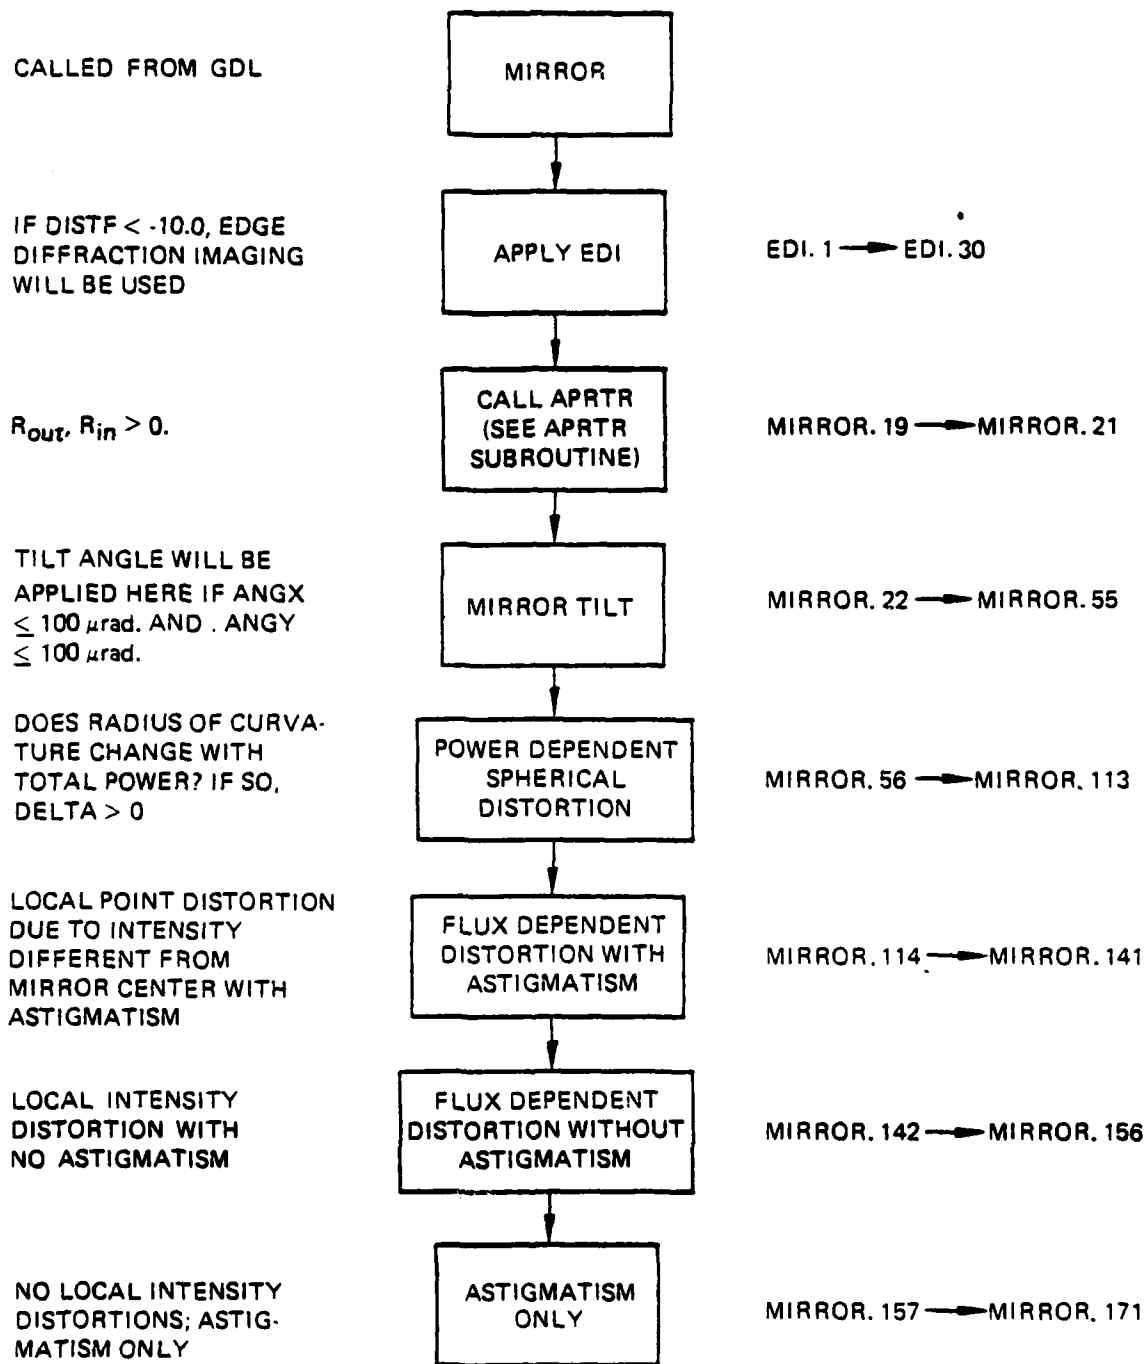

Figure 38. Subroutine MIRROR organization.

The routine first tests for the option of edge diffraction imaging in which the outer annular edge of the mirror has a radius of curvature different from the mirror. When this option is used the MIRROR subroutine must be called separately to apply EDI.

The subroutine must be called again for the rest of the mirror.

The routine then apertures the field to the size of the mirror and applies small mirror misalignments (angles less than 100 microradians) to the field. For large angles, the angle information is stored in ANGX and ANGY which are located in common MRPROP and used to later determine the location of the center of the field. The field itself is not altered for the large angles.

b. Revelant formalism -- A distortion-free mirror is applied to the field in Figure 39 by changing the optical path lengths of the field points. For example, apply a convex mirror to a plane wave.

Figure 59. Mirror transmission function relative to the complex field.

Note that the field at the edge has traveled  $2\delta_0$  more than the center. The size of the sag  $\delta(r)$  (Fig. 40) at any point  $r$  can be found from the sag formula:

$$(R_c - \delta)^2 + r^2 = R_c^2 \quad (135)$$

$$\delta \approx \frac{r^2}{2R_c} = \frac{x^2 + y^2}{2R_c}$$

Figure 40. Graphic representation of SAG.

Thus, to make the center of the field lead the edge by a factor of  $2\delta_0$ , the following transmission function is applied to the field:

$$u'(x,y) = T(x,y) u(x,y), \quad T(x,y) = e^{i \frac{2\pi}{\lambda} \left( \frac{x^2 + y^2}{R_c} \right)} \quad (136)$$

The sign convention used is a negative radius of curvature for a convex mirror. A concave mirror has a positive radius of curvature.

In addition to curvature, the MIRROR routine can apply power or flux dependent distortions to the field.

The power dependent mirror distortion can be applied given the center-to-edge maximum sag, DELTA, determined by design power, PWRDES. The incident power is then calculated and the sag reduced by the ratio of incident power to design power. For a ratio greater than one, it is assumed that the sag is that of the design power.

The flux dependence is applied assuming a distortion factor, DISTF, which weights intensity changes from the center of the field and thus applies an intensity-dependent phase factor to the field.

Astigmatism can be applied to the field in conjunction with the localized flux-dependent distortion or can be applied alone. Astigmatism is included if PHIAST is input (as a number greater than 0). PHIAST is the angle between the mirror normal and the optical axis (in degrees). The phase is altered by astigmatism by computing separate (sagittal and tangential) radii of curvature for the mirror and applying to vary the X and Y component of the phase field, respectively.

#### Argument List

ANX	Mirror tilt in X (about y-axis)
ANY	Mirror tilt in Y (about x-axis)
RADC	Radius of curvature of mirror (cm)
RIAOUT	Outside radius (cm)
RIAIN	Inside radius of annular mirror (cm)
XPOS	X-direction offset of mirror centerline from optical axis of beam (cm)
YPOS	Y-direction offset of mirror centerline from optical axis of beam (cm)
RFL	Mirror reflectivity - fraction 0.0 → 1.0
DELTM	Total power spherical distortion factor
DISTF	Flux distortion factor - local intensity distortion $f(I_{\text{local}} - I_{\text{center}})$ ; (cm/W/cm <sup>2</sup> )
RANULS	Radius to annulus for toric mirror option
RYOUT	Outside Y-dimension (from center) for a rectangular mirror (cm)
RYIN	Inside Y-dimension (from center) for a rectangular mirror (cm)
PHIAST	Angle of beam with respect to mirror normal (deg)

#### Relevant Variables

AKY	$2\pi/WL = 2\pi/\lambda$ where $\pi = 3.14159$
ANGX	Accumulative x-dim angle to trace field in cavity
ANGY	Accumulative y-dim angle to trace field in cavity

COSP Cosine of phase change  
 CUR Real array representing the complete wave amplitude field, i.e., Intensity (J) =  $\left[ \text{CUR}(J) \right]^2 + \left[ \text{CUR}(J-1) \right]^2$   
 DELTA DELTM, total power spherical distortion factor  
 FMF Square root of mirror reflectivity  
 PHASE Phase change at each point of wavefront  
 PHI Phase change in TORIC MIRROR and DIMPLE calculations  
 PPW Integrated power on mirror  
 RADCUR Negative focal length of mirror ( -f)  
 RMSAG Sagittal radius of curvature (astigmatism)  
 RMTAN Tangential radius of curvature (astigmatism)  
 SINP Sine of the phase change  
 WL Wavelength,  $\lambda$   
 WNDW Magnification factor for scaling power  
 XX  $X^2$ ; x-component of location, squared  
 YY  $Y^2$ ; y-component of location, squared

#### EDI (Edge Diffraction Imaging)

Power near the outer edge of the beam that would have been ordinarily lost through diffraction is partially recovered by incorporating a separate radius of curvature in an outer edge annulus, as shown in Equation 137 and Figure 41.

$$\Delta\phi = W_n \left[ (x^2 + y^2) - R_{in}^2 \right] / R_{EDI} \quad (137)$$

$$W_n = \frac{2\pi}{\lambda}$$

Figure 41. Edge diffraction imaging.

The real representation CUR of the complex amplitude field is modified as follows:

K2 = EVEN NOS

K2MI = ODD NOS

Real Part:  $CUR(K2) = CUR(K2-1) (\sin \emptyset) + CUR(K2) (\cos \emptyset)$

Im part:  $CUR(K2MI) = CUR(K2-1) (\cos \emptyset) - CUR(K2) (\sin \emptyset)$

This array is modified in the same way by the phase changes throughout this subroutine.

Mirror Tilt (<100  $\mu$ rad)

$$\Delta\phi = -2 \left[ (ANX)(X) + (ANY)(Y) \right] \frac{2\pi}{\lambda} \quad (138)$$

where

ANX => tilt in x-direction  $\sim$  radians

ANY => tilt in y-direction  $\sim$  radians

#### Power Dependent Spherical Distortion

This part of MIRROR subroutine calculates the phase change due to total power induced spherical distortion.

$$\Delta\phi = \frac{2\pi}{\lambda} \left[ \frac{(x^2 + y^2)}{R} \right] \quad (139)$$

where

$$R = R_{out}^2 / 2\delta$$

$$\text{and } \delta = \text{DELTA} = \text{MAX (Center) DISTORTION} \frac{(\text{Scaled for Power})}{P_{design}}$$

$$\text{DELTA} = \text{DELTA}^{(1)} \left( \frac{P_{incident}}{P_{design}} \right)$$

$$R_{out} = \text{Center to edge mirror radius}$$

(1) this is the input DELTA=DELT

Flux Dependent Distortion (No Astigmatism)

Flux Dependent Distortion + Astigmatism

$$\Delta\phi = \frac{2\pi}{\lambda} \left[ \frac{x^2}{R_{SAG}} + \frac{y^2}{R_{TAN}} \right] - \frac{2\pi}{\lambda} \delta_I (1-\text{Ref.}) 2 \frac{I_{CL} - I_{xy}}{(WNOW)^2} \quad (140)$$

where

$$R_{SAG} = RADC / \cos \phi_{ast}$$

and

$$R_{TAN} = RADC (\cos \phi_{ast})$$

where

RADC = radius of curvature of mirror (cm)

$\phi_{AST}$  = beam-mirror angle radians =  $\frac{\text{PHIAST} \pi}{180}$

$I_{CL}$  = Mirror centerline intensity

$I_{XY}$  = Local (X,Y) intensity

WNOW = VAMP power correction factor

$\delta_I$  = Flux distortion factor (cm/W/cm<sup>2</sup>)

Ref. = Mirror reflectivity

$$\Delta\phi = \frac{-2\pi}{\lambda} \delta_I (1-\text{Ref}) 2 \frac{I_{CL} - I_{xy}}{(WNOW)^2} \quad (141)$$

where,

$\delta_I$  = Flux distortion factor (cm/W/cm<sup>2</sup>)

$I_{CL}$  = Intensity at mirror center (W/cm<sup>2</sup>)

$I_{xy}$  = Intensity at coordinated x,y ( $W/cm^2$ )  
 Ref = Mirror reflectivity  
 WNOW = VAMP power correction factor

Astigmatism (Only)

$$\Delta\phi = \frac{2\pi}{\lambda} \left[ \frac{x^2}{R_{SAG}} + \frac{y^2}{R_{TAN}} \right] \quad (142)$$

where  $R_{SAG} = RADC / \cos \phi_{ast}$  (cm)  
 and  $R_{TAN} = RADC (\cos \phi_{ast})$  (cm)  
 where RADC = radius of curvature of mirror (cm)  
 $\phi_{ast}$  = beam - mirror (astigmatic) angle  
           = PHIAST  $\left( \frac{\pi}{180} \right)$

## 18. SUBROUTINE MIX

a. Purpose -- MIX calculates relaxation and pumping rates for use by subroutine KINET. The time constants which describe the various collisional processes are generated from quadratic fits to published data over a finite temperature range. The relaxation rates are then calculated from the time constants and the cavity gas mixture ratio. This routine does not require an argument list.

### Relevant Variables

TC2C	time constant for CO <sub>2</sub> (OVO) + CO <sub>2</sub> → CO <sub>2</sub> + CO <sub>2</sub>
TC2N	time constant for CO <sub>2</sub> (OVO) + CO <sub>2</sub> → CO <sub>2</sub> + N <sub>2</sub>
TC2O	time constant for CO <sub>2</sub> (OVO) + O <sub>2</sub> → CO <sub>2</sub> + O <sub>2</sub>
TC2W	time constant for CO <sub>2</sub> (OVO) + H <sub>2</sub> O → CO <sub>2</sub> + H <sub>2</sub> O
TC3C	time constant for CO <sub>2</sub> (OVO) + CO <sub>2</sub> → CO <sub>2</sub> (OVO) + CO <sub>2</sub>
TC3N	time constant for CO <sub>2</sub> (OOV) + N <sub>2</sub> → CO <sub>2</sub> (OVO) + N <sub>2</sub>
TC3W	time constant for CO <sub>2</sub> (OOV) + H <sub>2</sub> O → CO <sub>2</sub> (OVO) + H <sub>2</sub> O
TPMP	time constant for N <sub>2</sub> (V=1) + CO <sub>2</sub> → N <sub>2</sub> + CO <sub>2</sub> (001)
TTRD	$T_s^{-1/3}$
TTRD2	$T_s^{-2/3}$
RC2	relaxation rate for CO <sub>2</sub> (OVO) → CO <sub>2</sub> (000)
RC3	relaxation rate for CO <sub>2</sub> (OOV) → CO <sub>2</sub> (OVO)
RN2	nitrogen mispump rate (pumps CO <sub>2</sub> bending mode)
RPUMP	pumping rate for upper level excitation

b. Relevant formalism -- The CO<sub>2</sub> V-V and V-T relaxation rates, the pumping rate and the nitrogen mispump rate are computed by

$$R = P_S \sum_i x_i / \tau_i \quad (143)$$

where  $P_S$  is the static pressure,  
 $x_i$  are the appropriate species mole fractions,  
and  $\tau_i$  are their associated time constants.

The time constants,  $\tau_i$ , associated with the various collisional processes are computed by an exponential quadratic fit to published data. The general form is:

$$\tau_i = \exp \left( a_i T_S^{-\frac{2}{3}} + b_i T_S^{-\frac{1}{3}} + c_i \right) \quad (144)$$

#### 19. SUBROUTINE MODER:

a. Purpose -- Subroutine MODER is designed to orthogonalize one complex field with respect to another, and to excite a higher order mode for bare resonator mode studies. The fundamental relationships are from the Siegman-Miller paper (Ref. 13). Figures 43, 44, and 45 are flow charts for the Subroutine MODER Organization.

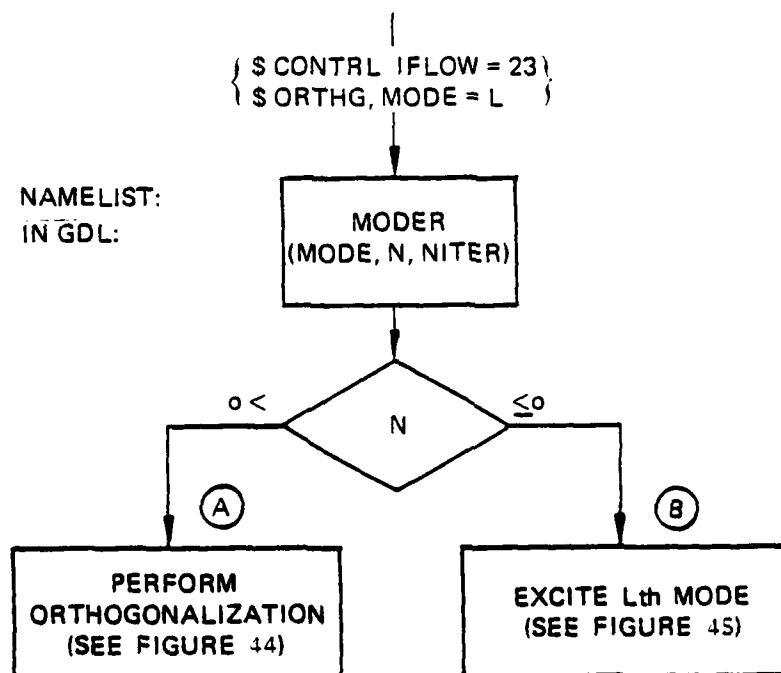

Figure 43. Subroutine MODER organization.

13. Siegman, A. E. and H. Y. Miller, "Unstable Optical Resonator Loss Calculations Using the Prony Method," Applied Optics, 9, p. 2729, 1970.

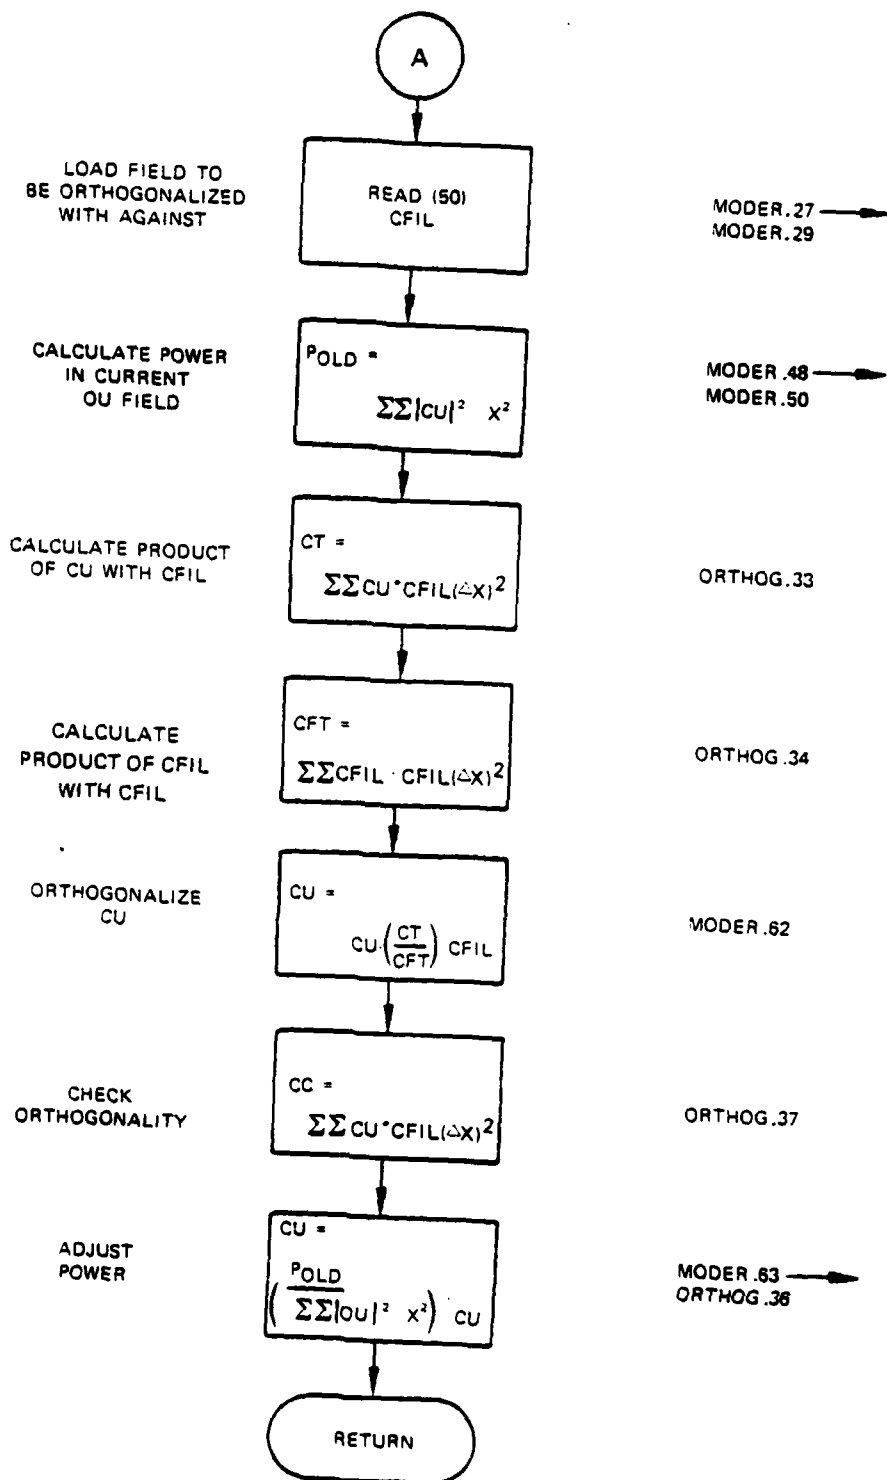

Figure 44. Perform orthogonalization.

Figure 45. Mode excitation.

b. Relevant formalism -- The orthogonality condition satisfied for symmetric kernel calculations is

$$\iint_R f(x,y)g(x,y) \, dx dy = 0 \quad (145)$$

where

R = calculation region of interest

f,g = two arbitrary complex fields, described here at equispaced discrete points.

The procedure is implemented by a Gramm-Schmidt orthogonalization, to create a new field, h(x,y) from two known fields. Assume

$$h(x,y) = f(x,y) + cg(x,y) \quad (146)$$

where,

$c$  = complex constant

$g$  = field with which orthogonalization takes place.

then 
$$\iint_R dA g h = 0 \quad (147)$$

So 
$$c = - \left( \frac{\iint_R f g dA}{\iint_R g g dA} \right)$$

So 
$$h = f - \left\{ \frac{\iint_R f g dA}{\iint_R g g dA} \right\} g \quad \forall (x, y) \in R$$

Numerically this becomes,

$$h_{ij} = f_{ij} - \left\{ \frac{\sum_i \sum_j f_{ij} g_{ij}}{\sum_i \sum_j g_{ij}^2} \right\} g_{ij} \quad \forall (x_{ij}, y_{ij}) \in R \quad (148)$$

Additionally, impose the condition that

$$h_{ij} = \left[ \frac{\iint_R |f|^2 dA}{\iint_R |h|^2 dA} \right]^{1/2} h_{ij} \quad (149)$$

then  $h_{ij}$  is the new field which is orthogonal with respect to  $g_{ij}$ , and has the same power as the initial field  $f$ .

Additionally, MODER is structured to excite the azimuthally-varying phase factor for the generation of higher order modes. In cylindrical coordinates, the modes of a bare resonator may be written as:

$$U_{ne}(r, \theta) = \phi_{ne}(r/a) e^{-j1\theta} \quad (150)$$

where,

$$0 \leq \theta \leq 2\pi$$

an arbitrary (convex mirror) scaling factor

$$l = \pm 1, \pm 2, \dots$$

$$n = 0, 1, 2, \dots$$

Higher order modes in bare resonators are initially excited as

$$f'(x,y) = \left[ \varepsilon^{-j l \tan^{-1}(y/x)} \right] f(x,y) ; \quad \frac{x^2 + y^2}{a^2} \leq 1 \quad (151)$$

and in discrete form as

$$f_{ij} = \exp \left[ -j l \tan^{-1}(y_i/x_i) \right] f_{ij}$$

where  $f_{ij}$  is the SOQ complex field distribution.

c. Fortran

Argument List:

N Integer variable denoting the calculation path within the subroutine

N<0 excite the  $L^{\text{th}}$  mode and return

N>0 Perform Orthogonalization

L Order of Mode to be excited

L = 1,2, .....

## 20. SUBROUTINE OUTPUT

a. Purpose -- This routine generates three intensity amplitude and phase printer slice plots through the field. They are along the x-axis, the y-axis, and the "diagonal," defined by the diagram in Figure 46. Figure 47 shows the flow chart for this subroutine.

Figure 46. Intensity amplitude and phase printer slice plots.

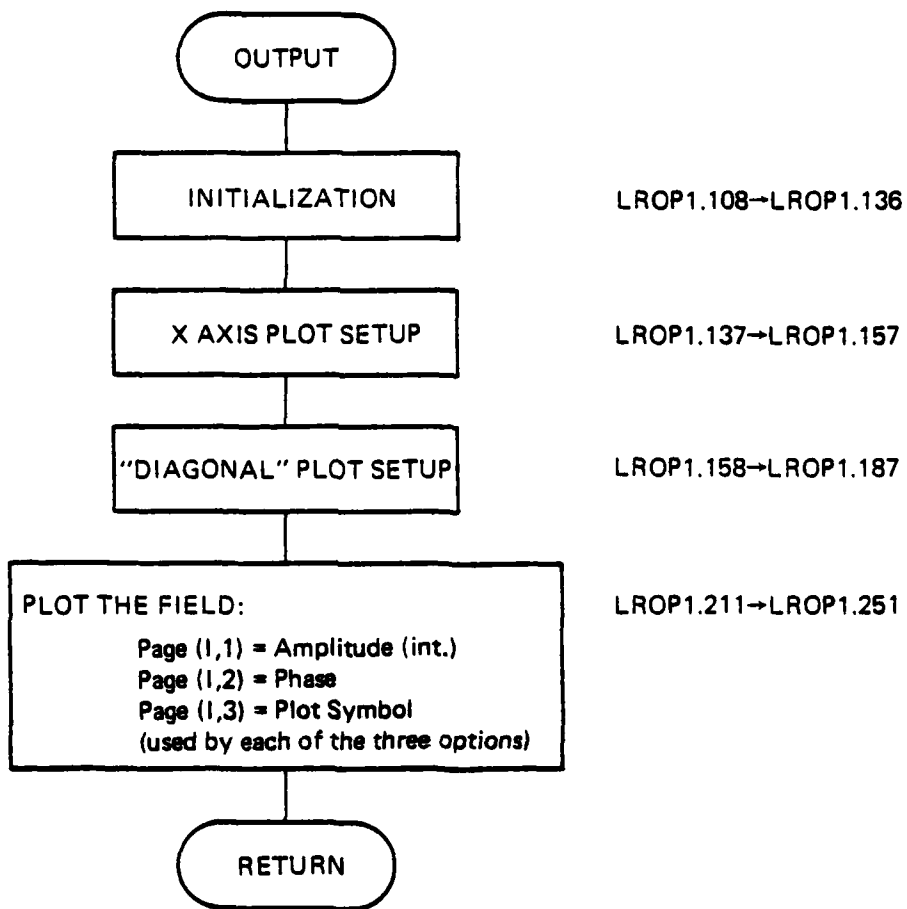

Figure 47. Subroutine OUTPUT flow chart.

b. Relevant formalism -- The slice plot uses 100 available spaces per line for plot information. The point printed shows the percent of maximum amplitude or intensity e.g., if the intensity or amplitude is 35 percent of the maximum, a symbol is printed in the 35th column. Similarly the phase is plotted from -180 to 180 degrees with zero-phase at the center. The corresponding maximum intensity amplitude is also printed out with the appropriate spatial coordinates.

c. Fortran

Argument List

CU	field to be plotted
NP2	number of points in the y-direction
NP1	number of points in the x-direction
x	coordinate array
N	number of plots (1 to 3)
	(N) = 1 → x only
	2 → x and diagonal
	3 → x, diagonal, and y

if  $N < 0$ , the constant J orders used is  $NP/2$  instead of  $NP1/2$ . This parameter is used when gain/phase slice plots are made.

UMAX - maximum intensity amplitude of the field. It is used to establish the field point to be plotted at 100 percent.

X-AXIS - if true, the x axis plot is generated

DIAG - if true, the "diagonal" plot is generated

Y-AXIS - if true the y axis plot is generated.

No common variables are modified.

No other subroutines are called from this one.

Computer printouts for the OUTPUT subroutine follow.

## 21. SUBROUTINE PLTOT

Subroutine PLTOT is called at the end of subroutine QUAL to calculate and generate a printer plot of far field power versus radial distance in  $R\lambda/D$  units. The integrated fractional power to several far field radii are calculated by multiple calls to subroutine POWWOW. The power and radius values are stored by PLTOT in array form. The arrays are then tabulated. A simple printer plot is also generated without the necessity of an interpolation scheme or other formal calculations.

Figure 48 is the Subroutine PLTOT flow chart and is followed by the PLTOT computer printouts.

### Argument List

DB	near field beam diameter
DX	grid spacing in far field, $R\lambda/D$ units
IMAX	number of field points across grid
IPLT	flag - not used
PT	total near field power
RMAX	not used
TITLE	run identification
WL	wavelength
XCEN	X-position of center of interest
XX	X-position array
YCEN	Y-position of center of interest
Z	far field intensity array
ZMAX	not used

## 22. SUBROUTINE POWWOW

Calls: N/A

Called by: QUAL

a. Purpose -- POWWOW is called by QUAL to apply an aperture to the far field intensity field for computing power in the bucket. Figure 49 shows the POWWOW flow chart, followed by the POWWOW computer printouts.

POWWOW passes the intensity field, x and y centroid locations, and bucket size. It returns the power in the bucket in parameter PRB (PWR).

POWOW defines a radius function, RD, for converting rectangular coordinates to a radius bucket size. Each x,y coordinate is searched to determine if it is within the bucket. If so, the power at that point is added to the sum for the bucket.

After all locations have been checked, control is returned to QUAL along with the power number.

b. Relevant formalism -- Each grid point (X,Y) lies at the center of a square  $\Delta X$  on a side. In the logic to determine whether a point falls within the radius of interest, an attempt is made to account for grids which fall partially within the radius, RAD. These points are weighted between 0 and 1 according to

$$P = (RAD - R_{\min}) / (R_{\max} - R_{\min})$$

where

P is the weighting factor,

$R_{\max}$  is the radius to the furthest corner of the grid, and

$R_{\min}$  is the radius to the nearest corner of the grid.

All grid points with  $R_{\max}$  less than RAD are given a weight of 1, all grid points with  $R_{\min}$  greater than RAD are weighted 0.

#### Argument List

AA	far field intensity array
DX	separation of far field points
NPTS	number of array points in one dimension
PWR	power in the bucket - returned to calling routine
RAD	radius of far field bucket
XAR	X-position array for intensity field
XCEN	X-position of center of interest
YCEN	Y-position of center of interest

#### Relevant Variables

DS	area associated with a grid point
PER	weighting factor for a grid point, between 0 and DS
X	X-position of grid point
Y	Y-position of grid point

## 23. SUBROUTINE QUAL

Called by: MAIN  
 Calls: TILT  
 STEP  
 CENBAR  
 POWWOW

QUAL, entered with a call from MAIN, is used to calculate quality of complex field. Figure 50 is the flow chart for the QUAL subroutine. Subroutine QUAL computer printouts follow Figure 50. A decision is made whether to use the COMMON complex field or whether to read one in from tape. A decision is then made as to whether or not to save whatever input complex field is used. This is for later restoration.

Variables are initialized and, based on the call statement input variables, a decision is made whether or not to apply a phase correction to the complex field, that is, should tilt and/or spherical components be removed? If not, QUAL branches to the lens section.

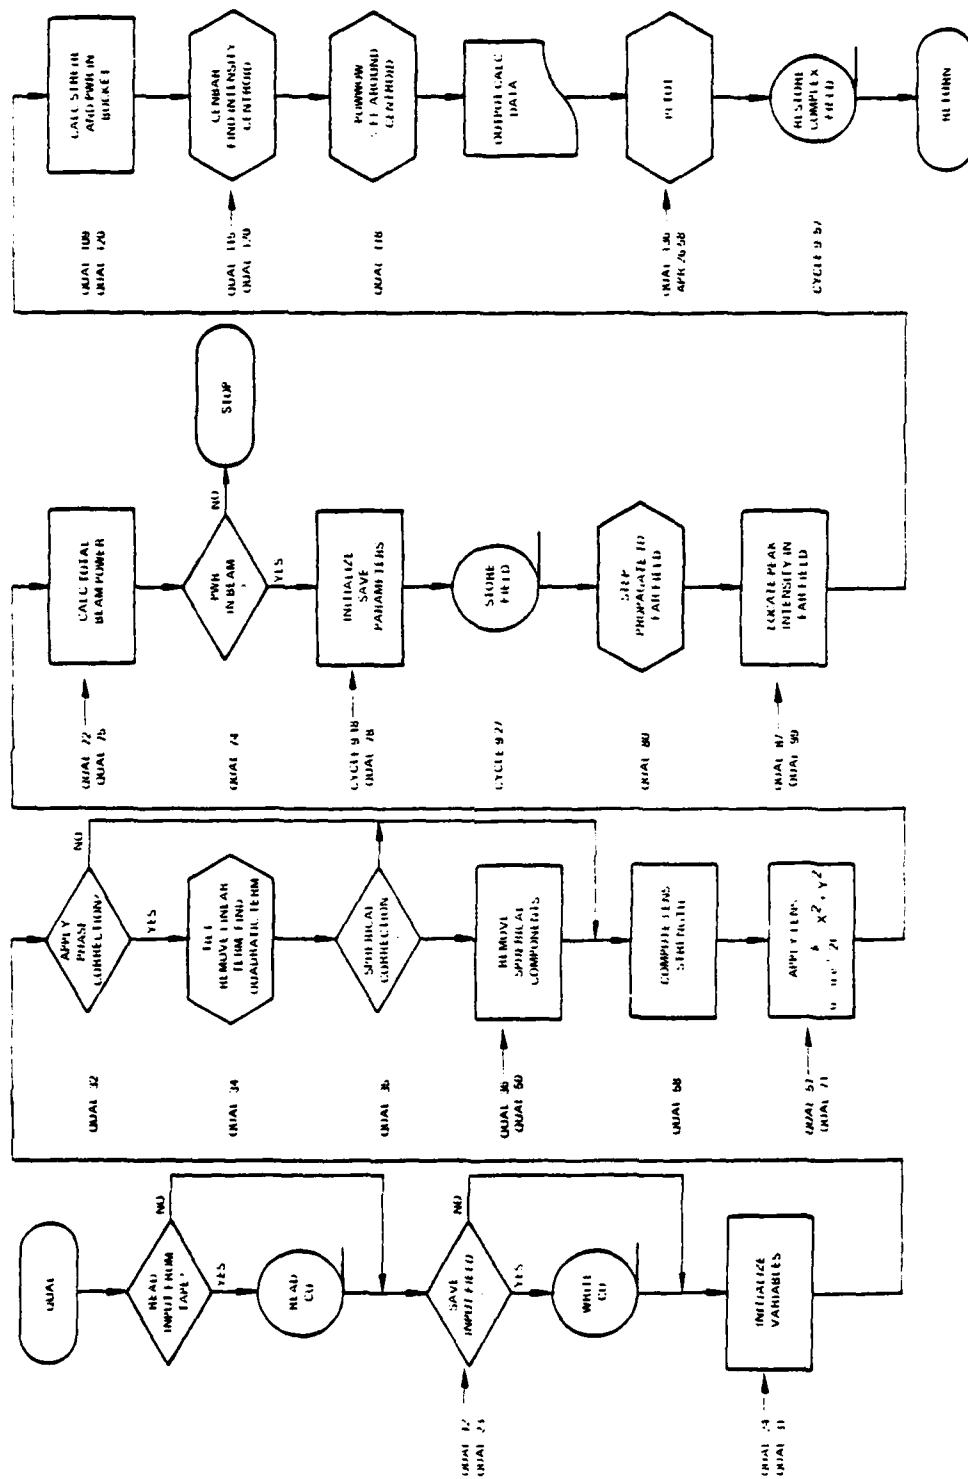

Figure 50. Subroutine QUAL flow chart.

If yes, then a call is made to subroutine TILT and the linear and quadratic phase components are removed. If spherical components are to be removed, then this is done. If not, control passes to the lens section.

The lens strength required to bring the beam down to a specified radius is computed. This is then applied to the field, CU, via the relation

$$U = U \exp \left[ i \frac{k}{2f} (x^2 + y^2) \right] \quad (152)$$

The total beam power as transformed by the lens is then calculated. If there is no power in the transformed beam, an error message is output and the job stopped. Otherwise, some saving parameters are initialized and the transformed field is saved on tape.

Subroutine STEP is called to take the transformed beam to the far field. The location of the far field peak intensity is found. Strehl and power in the bucket are calculated. Subroutine CENBAR is called to find the percent of far field centroid (intensity). Subroutine POWWOW is called to find the percent of far field power in a given radius around the centroid. All of the calculated data is printed and subroutine PLTOT is called for beam quality plots.

QUAL then restores the complex field to what it was at entry and control is returned to MAIN.

#### 24. SUBROUTINE REGAIN

Called from: GDL

Calls: BLUMIT, CPUTIM, FUHS, GAINXY, ISOCV, SIMPGG, VINO

a. Purpose -- REGAIN is primarily a driver program to direct the recalculation of the cavity gain medium at the end of each iteration as shown by Figure 51. Subroutine REGAIN computer printouts follow Figure 51. The routine controls the type of kinetics calculation (numerical or analytical closed form), calculation of the FUHS effect on the medium density, generation of plots, and input/output of medium data on disk. Most of the control for this routine is read in from subroutine CAVITY.

b. Relevant formalism - The only formal calculations performed in REGAIN are the summation of cavity aerodynamics and FUHS effect induced optical path variations, and the averaging of newly calculated gain distribution with that of the previous iteration. A simple linear averaging or weighting algorithm is used:

$$G = (G_o (1-A) + G_c A) \exp \left( (2\pi/\lambda) \text{ OPD} \right) \quad (153)$$

where

$G_o$  is the amplitude gain field from the previous iteration,

$G_c$  is the newly calculated amplitude gain field,

OPD is the sum of optical path differences,

$\lambda$  is the wavelength.

#### Argument List

NCT            the number of cavity elements in the resonator

NIT            the iteration number

#### Commons Modified

/CCG/

#### Variables Modified

CG            the complex gain field

#### Relevant Variables

AVGG            weighting factor for averaging new and old gain arrays -  
defined by input to GDL

IBASE            integer reference number to control reading and writing  
power densities, gain, etc. to and from disk

IPDEN\*            flag for plotting power densities

IUSE\*            flag for FUHS calculation

NGPLOT\*            flag for plotting gain fields

NGTYPE\*            flag for controlling type of kinetics calculation

NSA\*            number of gain/phase segments

NXA\*            number of points in flow direction

NYA\*            number of points across cavity (side-to-side)

\*Defined by input to CAVITY

```

## 25. SUBROUTINE RGRD

This routine regrid a complex amplitude field by adding zeroes to the array on all sides of the input field. Figure 52 is the flow chart for subroutine RGRD. Points added have the same separation as the original field. No interpolation or other formal calculation is necessary. Use of this routine has the effect of increasing the guard band around the field.

### Argument List

NRGD      desired number of grid points across field

### Relevant Variables

DX          separation of grid points before and after regridding  
INDX        counter or index used to locate old grid within the new grid  
NSQR        total number of points in regridded field

### Commons Modified

/MELT/

### Variables Modified

CFIL        temporary field storage array  
CU          complex amplitude field  
NPTS        number of grid points in x-dimension  
NPY        number of grid points in y-dimension  
X          x-position array

## 26. SUBROUTINE ROSN

a. Purpose -- The purpose of subroutine ROSN is to provide an accurate and rapid numerical interpolation subprogram for the evaluation of cavity-induced density perturbations. The subroutine uses cubic spline processed data representing aerodynamically parameterized  $\frac{\Delta \rho}{\rho}$  data to interpolate to the cavity mesh for the run in question as shown in the ROSN subroutine flow chart (Fig. 53). Subroutine ROSN requires that the user specify the relevant cubic spline coefficients and  $\frac{\Delta \rho}{\rho}$  values. The subroutine calculates  $\Delta \phi$  for an arbitrary cavity mesh point, (x,y).

Figure 52. Subroutine RGRD flow chart.

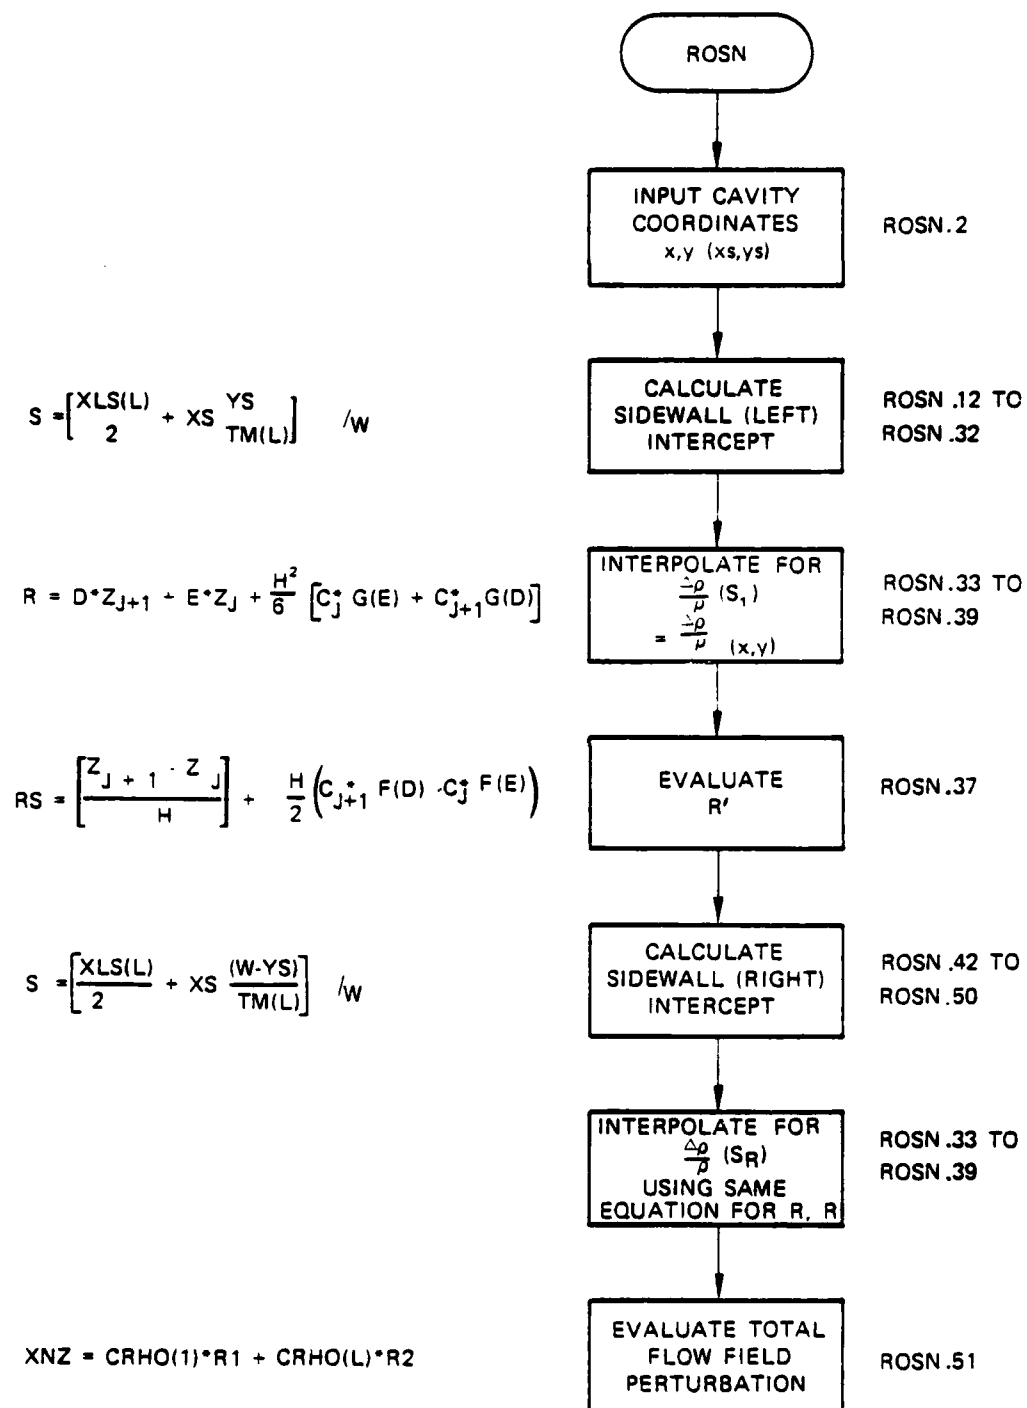

Figure 53. Subroutine ROSN flow chart.

b. Relevant formalism -- The SOQ Cavity coordinate system represents a regular mesh upon which many perturbations are applied. High Mach number flow produces ordered density gradients which may degrade beam phase relationships. Given arbitrary flow field interferometry it is possible to parameterize fringe shift ( $\frac{\Delta \rho}{\rho}$  or  $\Delta \text{OPD}$ ) as a function of sidewall parameter  $s$ , where  $s$  is determined from the cavity sidewall projection of Mach lines, as shown in Figure 54.

Figure 54. Fringe shift as a function of sidewall parameter.

From interferometry data and the above concept of sidewall projected data, the following parametric curves may be defined:

The curves shown in Figure 55 are fit using cubic splines, and the table or arrays of  $\frac{\Delta \rho}{\rho} = f(s^*)$  and  $C = g(s^*)$  (spline coeff) are stored in program DENSY. Subroutine ROSN is used to interpolate from  $(x,y)$  in the cavity to equivalent sidewall position  $s_{\text{right}}$  and  $s_{\text{left}}$  to determine using the above spline coefficients, an interpolated value of  $\frac{\Delta \rho}{\rho} \Big|_{\text{left}} = f(s_{\text{left}}) = H(x,y)$

$$\frac{\Delta \rho}{\rho} \Big|_{\text{right}} = g(s_{\text{right}}) = K(x,y) \quad (154)$$

Figure 55. Parametric curves of Mach lines.

The  $\left(\frac{\Delta\rho}{\rho}\right)$  at the point  $(x,y)$  is given, from supersonic flow theory as:

$$\left.\frac{\Delta\rho}{\rho_{CL}}\right|_{\text{Total}} = \left.\frac{\Delta\rho}{\rho_{CL}}\right|_{\text{left}} + \left.\frac{\Delta\rho}{\rho_{CL}}\right|_{\text{right}}$$

$$\Delta\phi = \frac{2\pi}{\lambda} C \left.\frac{\Delta\rho}{\rho_{CL}}\right|_{\text{Total}} \rho_{CL}$$

$$\Delta\phi = \Delta\phi(x,y)$$

$$\left(\frac{\Delta\rho}{\rho}\right) = \frac{\Delta\rho(x,y)}{\rho}$$

The Spline interpolator is:

$$\begin{aligned}
R = & \frac{S^* - S_i}{S_{i+1} - S_i} \left( \frac{\Delta \rho}{\rho} \right)_{i+1} + \frac{S_{i+1} - S^*}{S_{i+1} - S_i} \left( \frac{\Delta \rho}{\rho} \right)_i + \left[ \frac{(S_{i+1} - S_i)^2}{6} \right] \\
& * \left\{ [C_i] \left\langle \left( \frac{S_{i+1} - S^*}{S_{i+1} - S_i} \right) - \left( \frac{S_{i+1} - S^*}{S_{i+1} - S_i} \right) \right\rangle \right. \\
& \left. + [C_{i+1}] \left\langle \left( \frac{S^* - S_i}{S_{i+1} - S_i} \right)^3 - \left( \frac{S^* - S_i}{S_{i+1} - S_i} \right) \right\rangle \right\}
\end{aligned} \tag{155}$$

The interpolator is evaluated for each of a right and left wall contribution along the appropriate Mach line.

## 27. SUBROUTINE LINTERP

a. Purpose -- This subroutine is used within the SOQ code to linearly interpolate sidewall projected  $\frac{\Delta \rho}{\rho}$  cavity density information from sidewall projection to the cavity mesh. Data  $\frac{\Delta \rho}{\rho}$  are stored in compressed form as univariate curves of  $\frac{\Delta \rho}{\rho}$  versus sidewall projection parameters s, from which  $\frac{\Delta \rho}{\rho}$  at any point in the GDL cavity may be obtained as shown in Figure 56.

Figure 56.  $\Delta\rho/\rho$  cavity density information.

The interpolated  $\frac{\Delta\rho}{\rho}$  value is calculated to determine the equivalent flow-induced lens which is to be applied to the propagating wavefront. The lens is the result of flow-induced inhomogenities such as ordered density gradients (weak shocks) and uneven thermal distribution.

The LINTERP subprogram (Fig. 57) calculates the sidewall parameters from interpolated cavity position  $(x,y)$  and Mach angle. With "s" determined for both right and left cavity sidewall projections a  $\frac{\Delta\rho}{\rho}$  contribution can be determined for both sidewalls and linearly combined to give  $\left(\frac{\Delta\rho}{\rho}\right)_{\text{TOTAL}} = f(x,y)$ .

b. Relevant formalism

Left Intercept:

$$\tan\theta = \frac{y}{(x-x_{LI})} \quad x_{LI} = -\frac{y}{\tan\theta} + x \quad (156)$$

where

$(x,y)$  = interpolate position  
 $x_{LI}$  = Left intercept  
 $\tan\theta$  = tangent of Mach angle

sidewall parameter s

$$s_L = \frac{x_{LI}}{W} = \frac{(x-y/\tan\theta)}{W}$$

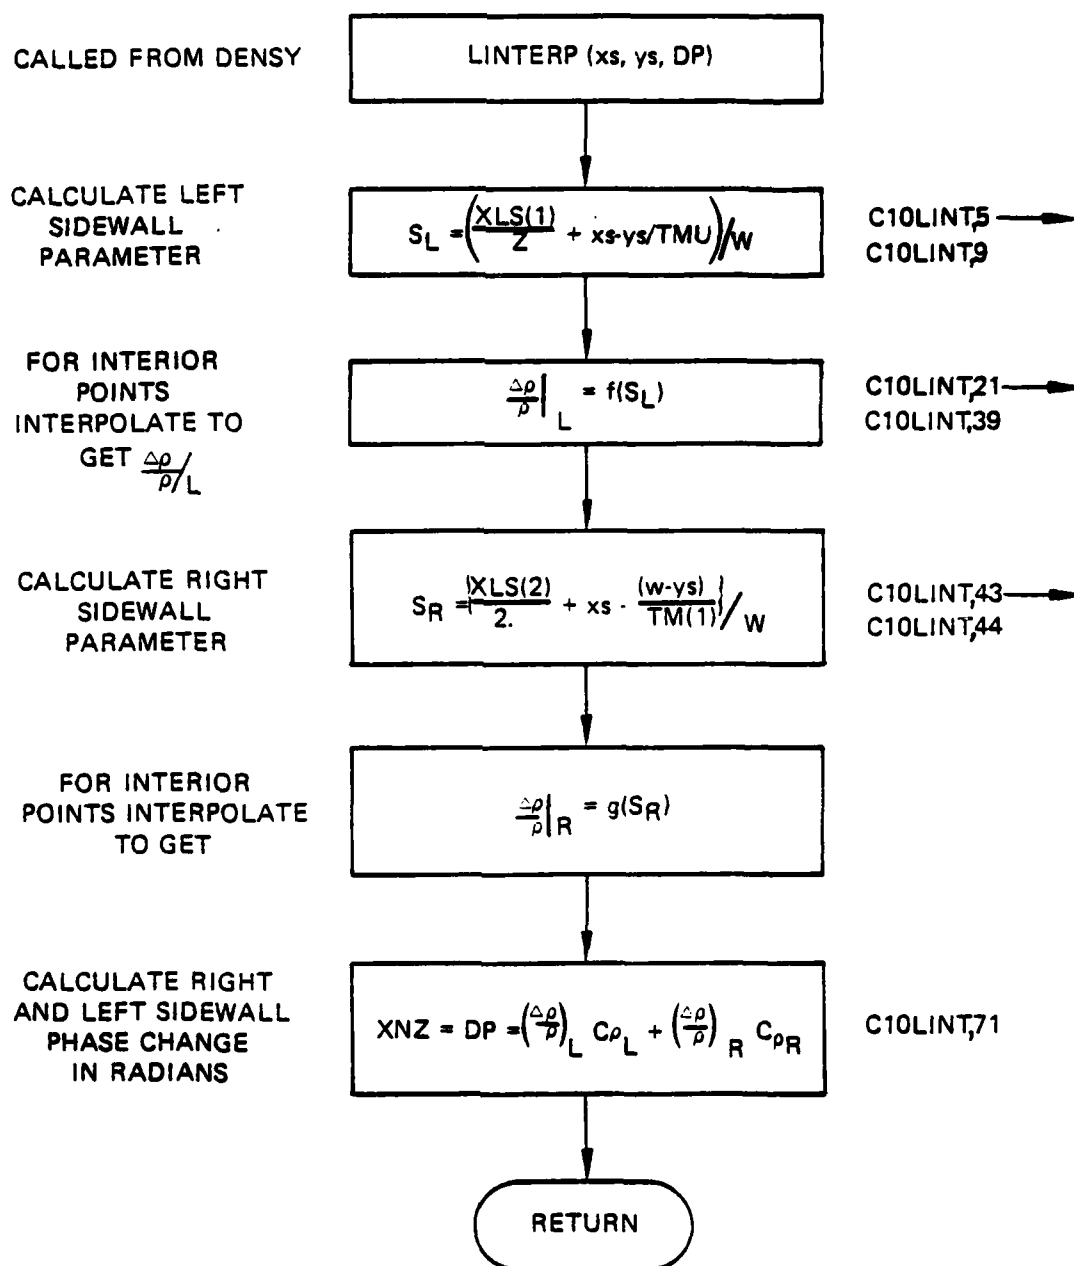

Figure 57. Subroutine LINTERP organization.

Right Intercept:

$$\tan \theta = \frac{w-y}{x-x_{R_I}} \quad (157)$$

$$(x - x_{R_I}) \tan \theta = (w-y) - x \tan \theta$$

$$x_{R_I} = \frac{-(w-y)}{\tan \theta} + x$$

$$S_R = \frac{x_{R_I}}{W} = \frac{x-(w-y)/\tan \theta}{W} \quad (158)$$

where

w = cavity width

$\tan \theta$  = tangent Mach angle

## 28. SUBROUTINE ROSN6

a. Purpose -- Subroutine ROSN6 (flow chart organization shown in Fig. 58) is incorporated into the SOQ code to allow inclusion of the cavity density field from direct interferogram data reduction. The data from interferometry are assumed to have been fit in the y (parallel to NEP) direction by cubic splines, using spaced points (not necessarily equal).

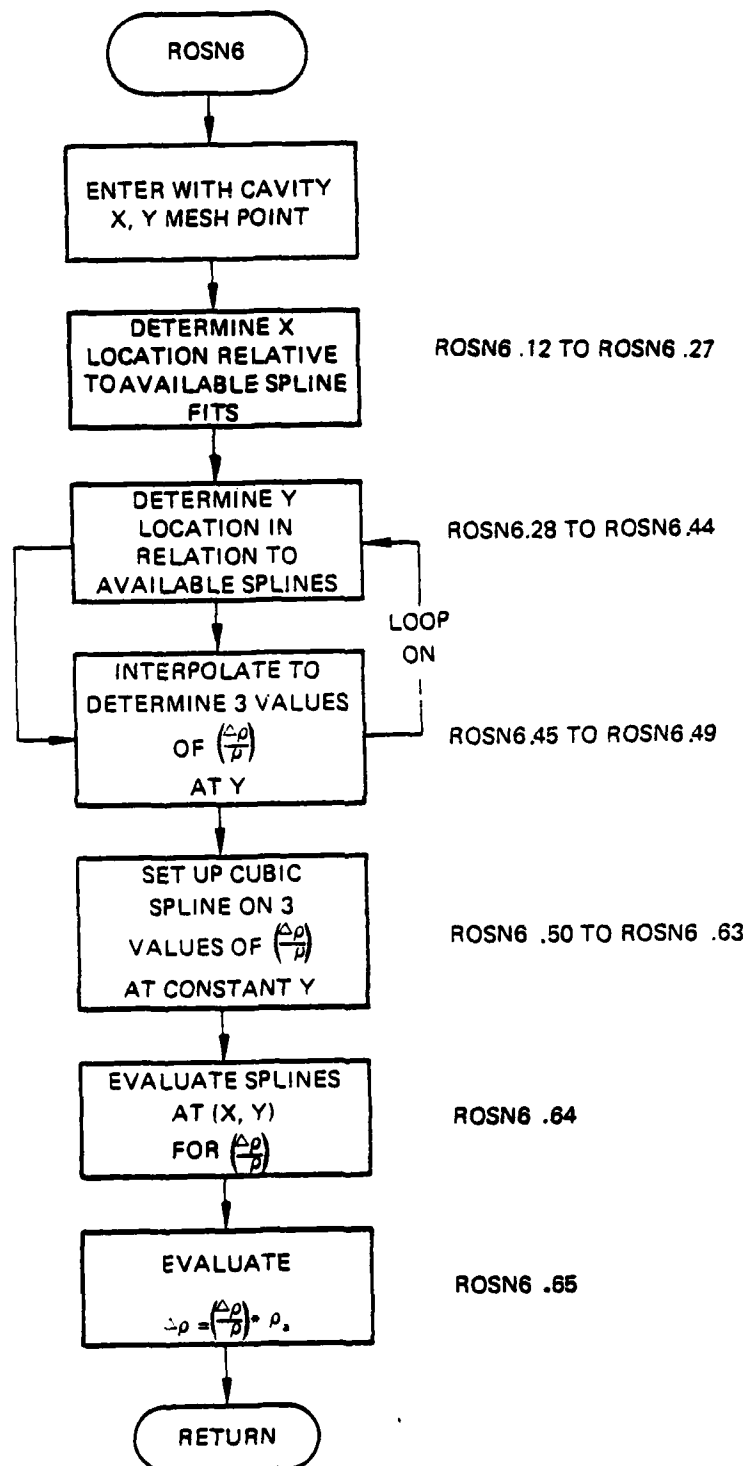

Figure 58. Subroutine ROSN6 organization.

Subroutine ROSN6 is a bivariate interpolation of the spline fit data using cubic splines.

b. Relevant formalism -- Subroutine ROSN6 uses the following procedure to interpolate the available spline data for an arbitrary cavity mesh point,  $(x,y)$ , shown in Figure 59.

- (1) Locate \* in the spline fit data.
- (2) Interpolate, using the spline fits at constant  $y$ , for the value of  $\frac{\Delta\rho}{\rho}$  at the nearest three  $x$  values,  $(\Delta)$ .
- (3) Construct a cubic spline in the direction  $(x_i, y^*)$  and evaluate at  $(x^*, y^*)$
- (4) Modify  $\frac{\Delta\rho}{\rho_{CL}}(x^*, y^*)$  by  $\frac{\Delta\rho}{\rho_{CL}}(x^*, y^*)$  to obtain  $\Delta\rho$  in the desired units.

See page 214 for subroutine ROSN6 computer printouts.

Figure 59. Available spline data for an arbitrary cavity mesh point.

## 29. SUBROUTINE SIMPGG

a. Purpose -- SIMPGG is used to calculate loaded gain for GDL cavities. It uses the E. A. Sziklas closed-form gain solution as derived in Reference 1, instead of numerically solving the appropriate GDL kinetics differential equations. SIMPGG also finds the intensity emitted at the gain/phase segment for use in FUHS. Figure 60 shows the SIMPGG organization.

b. Relative formalism -- The effect of the interaction of the light with the medium results in an amplification of the light beam as well as a phase change. Analytically this effect on the field is written

$$U(x,y) = t(x,y)U(x,y)$$

(159)

with

$$t(x,y) = e^{\frac{1}{2}g(x,y)\Delta L} e^{-i \frac{2\pi}{\lambda} \Delta n \Delta L}$$

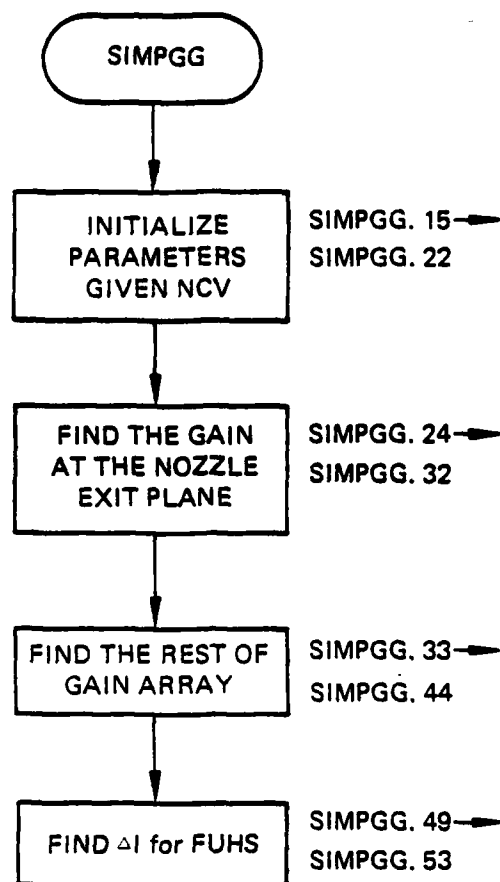

Figure 60. Subroutine SIMPGG organization.

$\Delta L$  is width of the medium under consideration,  $g(x,y)$  is the loaded gain coefficients and  $\Delta n(x,y)$  is change in index of refraction due to density variations.

The factor of  $1/2$  in the exponent is due to the fact that gain is intensity, not amplitude, related:

$$I_{OUT} = I_{IN} e^{g\Delta L} = G I_{IN} \quad (160)$$

where

$$I = |u|^2$$

SIMPGG determines  $g(x,y)$  analytically using expression

$$g(x,y) = \left[ \frac{g_o(x,y)}{1 + I(x,y)/I_{SAT}} \right] e^{\left( \frac{-X_{CO_2}^3}{X_{N_2} V} \right) \int_{x_o}^x dx \frac{I(x,y)}{I_{SAT} + I(x,y)}} \quad (161)$$

and using the trapizoidal rule for the integral, where  $g_o(x,y)$  is the small-signal gain coefficient found in subroutine GAINXY.

Note that

$$g(x,y) \Big|_{I(x,y) = 0} = g_o(x,y) \quad (162)$$

$I_{sat}$  is the "saturation intensity"

$$I_{SAT} = \frac{h\nu\beta}{\sigma} \quad (163)$$

where

$h\nu$  is the photon energy,  $\beta$  the lower laser level relaxation rate, and  $\sigma$  the optical cross section for the transition.  $I_{sat}$  is also defined in subroutine GAINXY.

Where the FUHS routine is to be called to calculate heat increase in the gas due to lower level decay, the intensity change in the beam is needed for each gain phase segment, thus giving the heat release.

Consider Figure 61 of a gain/phase segment

Figure 61. Gain/phase segment.

Then for each (I,J)

$$\Delta I = (I_1 + I_3) - (I_2 + I_4) \quad (164)$$

the quantity stored in the array PPD after a complete round trip is the average of the right running wave  $(I_1 + I_2)/2$  plus the average of the left running wave  $(I_3 + I_4)/2$ .

Therefore

$$PPD = (I_1 + I_2 + I_3 + I_4)/2 \quad (165)$$

but  $I_2 = GI$ , and  $I_4 = GI_3$

so  $\Delta I = (1-G) (I_1 + I_3)$

and  $PPD = \left(\frac{1+G}{2}\right)(I_1 + I_3)$

therefore

$$\Delta I = 2 \left(\frac{1-G}{1+G}\right) * PPD \quad (166)$$

Knowing the total power change due to  $\Delta I$  and the quantum efficiency  $\eta$ , the

total heat released is found. The factor  $\frac{1}{\Delta z} \left(\frac{1-\eta}{\eta}\right)$  is discussed in FUHS.

c. Fortran

Argument List

PPD = Total intensity (left running + right running waves) --

Becomes  $\frac{1}{\Delta z} \left(\frac{1-\eta}{\eta}\right) \Delta I$  for use in FUHS

GG = Gain =  $e^{-g\Delta z/2}$

NCV = cavity number

The following is from Reference 1 and is included for the convenience of the reader.

The gain coefficient for a gas dynamic laser is described with the aid of a simple three-level model representing a flowing  $N_2$ - $CO_2$  system interacting with a  $10.6\mu$  beam. The relevant energy-level structure is illustrated schematically in Figure 62. The upper (001) and lower (100) laser levels of  $CO_2$  are designated a and b, respectively. The symbols  $n_a$  and  $n_b$  denote the population densities occupying these levels. The first excited vibrational level of  $N_2$  is nearly resonant with the upper laser level. The population density  $N$  is nearly resonant with the upper laser level. The population density  $N$  in this level preferentially pumps the upper laser level. Since the ground state  $CO_2$  and  $N_2$  populations, labelled  $n_0$  and  $N_0$ , are generally large compared to  $n_a$ ,  $n_b$ , and  $N$ , the magnitudes of  $n_0$  and  $N_0$  are relatively unaffected by transitions to and from the excited levels. Accordingly,  $n_0$  and  $N_0$  may be viewed as constants, i.e.,  $n_0/N_0 = CO_2/x_{N_2} = \text{constant}$  where  $x_{CO_2}$  and  $x_{N_2}$  are the mole fractions of  $CO_2$  and  $N_2$ .

Figure 62. Relevant energy level diagram for  $N_2$ - $CO_2$  system.

For steady flow in the x-direction the rate equations describing the spatial variation of the three relevant population densities  $n_a$ ,  $n_b$  and  $N$  are given by

$$v \frac{\delta n_a}{\delta x} = \Lambda N - (\alpha + \Gamma) n_a - (\sigma I / h\nu) (n_a - n_b) \quad (167)$$

$$v \frac{\delta n_b}{\delta x} = -\beta n_b = (\sigma I / h\nu) (n_a - n_b) \quad (168)$$

$$v \frac{\delta N}{\delta x} = \Gamma n_a - \Lambda N \quad (169)$$

Here,  $v$  is the flow velocity (assumed constant);  $\alpha$  and  $\beta$  are the relaxation rates of the upper and lower levels;  $\Lambda$  and  $\Gamma$  are the forward and backward pumping rates of the upper laser level;  $\sigma$  is the optical cross section for the laser transition;  $h\nu$  is the photon energy; and  $I$  is the beam intensity.

Since the pumping rates  $\Lambda$  and  $\Gamma$  are proportional to the ground state population densities  $n_o$  and  $N_o$ , respectively, it follows that

$$\Lambda / \Gamma = x_{CO_2} / x_{N_2} \quad (170)$$

Under typical GDL operating conditions  $x_{CO_2} \ll x_{N_2}$ . Also typically, the upper level decay rate is slow relative to the lower level decay rate, and the latter is slow relative to the backward pumping rate, i.e.,

$$\alpha \ll \beta, \Lambda \ll \Gamma \quad (171)$$

The beam is assumed to propagate in the z-direction. For purposes of analysis it is convenient to suppose that the transverse intensity profile at some axial station  $z$  can be divided into a series of constant intensity segments, as illustrated in Figure 63. For example, in the  $n^{th}$  segment ( $x_n < x < x_{n+1}$ ) the intensity distribution is approximated by the value  $I_n =$  constant. For the moment, the segment width  $x_{n+1} - x_n$  is left unspecified.

Figure 63. Step approximation to transverse intensity profile.

The gain coefficient for the laser transition is defined by

$$g(x, I) = \sigma(n_a - n_b) \quad (172)$$

We wish to solve for  $g = g(x, I)$  in the  $n^{\text{th}}$  segment ( $n = 1, 2, 3, \dots$ ) where  $I = I_n = \text{constant}$ . The upstream edge conditions  $n_a(x_n)$ ,  $n_b(x_n)$  and  $N(x_n)$  are presumed known from the solution in the adjacent upstream segment. By successive application of the  $n^{\text{th}}$  segment solution, commencing with the segment at the upstream edge of the beam, one can in principle solve for  $g$  throughout the optical cavity.

The advantage of the segmented description is that an exact solution can be found in a region of constant beam intensity. Moreover, under suitable approximations, to be discussed later, this sequence of exact solutions can be put in a simple analytical form suitable for application to a smoothly varying beam profile.

Applying the Laplace transform to equations (167) through (169), one obtains

$$\underline{a} \underline{b} = \underline{c} \quad (173)$$

where

$$\underline{a} = \begin{Bmatrix} s+\alpha+\Gamma+W_n & -W & -\Lambda \\ -W_n & s+\beta+W_n & 0 \\ -\Gamma & 0 & s+\Lambda \end{Bmatrix}$$

$$\underline{b} = \begin{Bmatrix} \tilde{n}_a \\ \tilde{n}_b \\ \tilde{N} \end{Bmatrix} \quad \underline{c} = \begin{Bmatrix} n_a(x_n) \\ n_b(x_n) \\ N(x_n) \end{Bmatrix}$$

Here,  $\tilde{n}_a(s) = (1/v) \int_{x_n} dx n_a(x) \exp \left[ -s(x - x_n)/v \right]$ , etc.,  
and  $W_n = \sigma I_n / h\nu$ .

Solving by  $\underline{b}$

$$n_a(s) = |\det|^{-1} \left[ (s+\beta+W_n) (s+\Lambda) n_a(x_n) + W_n (s+\Lambda) n_b(x_n) + \Lambda (s+\beta+W_n) N(x_n) \right] \quad (174)$$

$$n_b(s) = |\det|^{-1} \left\{ W_s (s+\Lambda) n_a(x_n) + \left[ (s+\alpha+\Gamma+W_n) (s+\Lambda) - \Lambda \Gamma \right] n_b(x_n) + W_n \Lambda N(x_n) \right\} \quad (175)$$

$$N(s) = |\det|^{-1} \left\{ (s+\beta+W_n) \Gamma n_a(x_n) + W_n \Gamma n_b(x_n) + \left[ (s+\alpha+\Gamma+W_n) (s+\beta+W_n) - W_n^2 \right] N(x_n) \right\} \quad (176)$$

Here,  $|\det|$  is the determinant of  $\underline{a}$  given by

$$|\det| = s^3 + k_2 s^2 + k_1 s + k_0 \quad (177)$$

where

$$k_2 \approx \beta + \Lambda + \Gamma + 2W_n$$

$$k_1 \approx \beta(\Lambda + \Gamma) + W_n(2\Lambda + \Gamma + \beta)$$

$$k_0 \approx \Lambda \beta (\alpha + W_n)$$

The approximate equality sign refers to the use of the first half ( $\alpha \ll \beta, \Lambda, \Gamma$ ) of the inequality 171.

Under the same approximation the roots of equation (177) are given by

$$r_1 \approx \frac{\Lambda \beta (\alpha + W_n)}{\beta (\Lambda + \Gamma) + W_n (2\Lambda + \Gamma + \beta)} \quad (178)$$

$$r_2 = \frac{1}{2} \left[ \Lambda + \Gamma + \beta + 2W_n - \sqrt{(\Lambda + \Gamma - \beta)^2 + 4W_n (W_n - \Lambda)} \right] \quad (179)$$

$$r_3 = \frac{1}{2} \left[ \Lambda + \Gamma + \beta + 2W_n + \sqrt{(\Lambda + \Gamma - \beta)^2 + 4W_n (W_n - \Lambda)} \right] \quad (180)$$

where  $|\det| = (s + r_1) (s + r_2) (s + r_3)$ .

In the absence of a beam ( $W_n = 0$ ) the roots  $r_1$ ,  $r_2$  and  $r_3$  have a simple physical interpretation.

$$\begin{aligned} r_1 &\rightarrow r_1^0 = \alpha \Lambda / (\Lambda + \Gamma) \\ r_2 &\rightarrow r_2^0 = \beta \\ r_3 &\rightarrow r_3^0 = \Lambda + \Gamma \end{aligned} \quad (181)$$

The value  $r_1^0$  defines the relaxation rate of the available laser energy (the upper laser level coupled to the vibrationally excited  $N_2$ ) in the absence of a beam;  $r_2^0$  describes the lower level decay; and  $r_3^0$  is the rate at which pumping equilibrium between the excited  $CO_2$  and  $N_2$  is established. Typically,  $r_1^0 \ll r_2^0 \ll r_3^0$ .

As  $W_n$  is increased from zero, the physical identification of the roots  $r_1$ ,  $r_2$ , and  $r_3$  becomes somewhat obscure. However, the inequality  $r_1 \ll r_2 \ll r_3$  appears to hold for all values of  $W_n$ . This feature leads to an important simplification.

\*Care must be exercised not to introduce the second inequality at too early a stage in the calculation.

Taking the inverse Laplace transform of equations (174) through (176) one obtains a solution in the form

$$n_a(x) = A \exp \left[ -r_1 (x-x_n)/v \right] + B \exp \left[ -r_2 (x-x_n)/v \right] + C \exp \left[ -r_3 (x-x_n)/v \right] \quad (182)$$

where A, B, and C are functions of the initial conditions  $n_a(x_n)$ , etc., and of the various rate constants. Similar expressions hold for  $n_b(x)$  and  $N(x)$ .

In the absence of a beam ( $W_n = 0$ ) this solution reduces to the simple form

$$\begin{aligned} n_a(x) = & \frac{\Lambda}{\Lambda + \Gamma} \left[ n_a(x_n) + N(x_n) \right] \exp \left[ -r_1^* (x-x_n)/v \right] \\ & + \left[ \frac{\Gamma n_a(x_n) - \Lambda N(x_n)}{\Lambda + \Gamma} \right] \exp \left[ -r_3^* (x-x_n)/v \right] \end{aligned} \quad (183)$$

$$n_b(x) = n_b(x_n) \exp \left[ -r_2^* (x-x_n)/v \right] \quad (184)$$

$$\begin{aligned} N(x) = & \frac{\Gamma}{\Lambda + \Gamma} \left[ n_a(x_n) + N(x_n) \right] \exp \left[ -r_1^* (x-x_n)/v \right] \\ & - \left[ \frac{\Gamma n_a(x_n) - \Lambda N(x_n)}{\Lambda + \Gamma} \right] \exp \left[ -r_3^* (x-x_n)/v \right] \end{aligned} \quad (185)$$

the quantity  $\left[ n_a(x) + N(x) \right]$ , describing the available laser energy, decays at the characteristic rate  $r_1^0$  while the quantity  $\left[ \Gamma n_a(x) - \Lambda N(x) \right]$ , describing the departure from pumping equilibrium, decays at the rate  $r_3^0$ .

When the beam intensity  $I_n$  is nonvanishing, the details of the solution become rather cumbersome, and successive application of this solution to a series of adjacent beam segments would be a tedious task. Fortunately this complexity can be largely eliminated with the aid of two physically reasonable assumptions.

The first assumption is that the segment widths  $\Delta x_n = x_{n+1} - x_n$  can be made somewhat larger than the characteristic lengths  $v/r_2$  and  $v/r_3$ . In other words, the intensity distribution  $I = I(x)$  is assumed to vary little over the characteristic lengths for lower level decay and pumping equilibrium. In this event the second and third terms in equation (182), evaluated at the downstream edge of the  $n^{\text{th}}$  segment, can be neglected.

If, in addition, the rate of stimulated emission  $W_n$  ( $n = 1, 2, 3, \dots$ ) is less than the pumping equilibrium rate  $\Lambda + \Gamma$ , it follows that pumping equilibrium can be assumed throughout the optical cavity, i.e.,

$$\Gamma n_a(x) \approx N(x) \quad (186)$$

Application of these approximations yields for the population difference between laser levels evaluated at the downstream edge of the  $n^{\text{th}}$  segment

$$\begin{aligned} n_a(x_{n+1}) - n_b(x_{n+1}) &= \frac{\beta(\Lambda + \Gamma) n_a(x_n)}{\beta(\Lambda + \Gamma) + W_n(2\Lambda + \Gamma + \beta)} \exp \left[ -r_1(W_n) \frac{\Delta x_n}{v} \right] \\ &\approx \frac{\beta}{\beta + W_n} n_a(x_n) \exp \left[ -r_1(W_n) \frac{\Delta x_n}{v} \right] \end{aligned} \quad (187)$$

where, in the latter expression, use has been made of the second half of the inequality (171).

By a similar procedure one finds

$$n_a(x_n) \approx n_a(x_{n-1}) \exp \left[ -r_1(W_{n-1}) \frac{\Delta x_{n-1}}{v} \right] \quad (188)$$

Repeated substitution of equation (188) into (187) gives

$$\begin{aligned} n_a(x_{n+1}) - n_b(x_{n+1}) &= \frac{\beta n_a(x_1)}{\beta + W_n} \exp \left\{ - \left[ r_1(W_n) \Delta x_n + r_1(W_{n-1}) \Delta x_{n-1} \right. \right. \\ &\quad \left. \left. + \dots + r_1(W_0) \Delta x_0 \right] / v \right\} \end{aligned} \quad (189)$$

If the segment widths  $\Delta x_n$  ( $n = 0, 1, 2, \dots$ ) are now viewed as "infinitesimals" equation (189) may be rewritten

$$\begin{aligned}
 n_a(x) - n_b(x) &= \frac{n_a(x_0)}{1+w(x)} \exp \left[ -\frac{1}{v} \int_{x_0}^x dx' r_1 \right] \\
 &= \frac{n_a(x_0)}{1+w(x)} \exp \left[ -\frac{r_1^* (x-x_0)}{v} \right] \exp \left[ -\frac{1}{v} \int_{x_0}^x dx' (r_1 - r_1^*) \right]
 \end{aligned}
 \tag{190}$$

where  $w(x) = \sigma I(x)/h\nu\beta$  and  $x_0$  defines a convenient reference station (e.g., the upstream edge of the beam).

Using the basic definition (172), the rate expressions (178) and (181), the identity (170), and the inequality (171), one finds on substitution into (190)

$$g(x) = \left[ \frac{g_0(x)}{1+w(x)} \right] \exp \left\{ -\frac{x_{CO_2} \beta}{x_{N_2} v} \int_{x_0}^x dx' \frac{w(x')}{1+w(x')} \right\}
 \tag{191}$$

where  $g_0$  is the small-signal gain coefficient given by

$$g_0(x) = g_0(x_0) \exp \left[ -\frac{x_{CO_2} \alpha (x-x_0)}{x_{N_2} v} \right]
 \tag{192}$$

It is instructive to note the physical significance of various terms appearing in equations (191) and (192). The term in square brackets in equation (191) is analogous to the usual gain expression for a homogeneously broadened line in a nonflowing laser medium. Here, however, the small-signal gain coefficient (192) is not constant, but decays exponentially with distance downstream. The nondimensional intensity  $w(x)$  measures the rate of simulated emission  $\sigma I/h\nu$  relative to the decay rate  $\beta$  of the lower level. For a nonflowing laser the value  $w = 1$  defines the saturation intensity of the medium.

The exponential factor in equation (191) represents a corrective term due to flow. The probability that an initially excited  $\text{CO}_2$  molecule will remain excited after traversing a beam is dependent on the beam profile encountered by the molecule upstream of the point in question. This explains the presence of an integral over the upstream flowpath in equation (191).

In summary, a simple approximate expression has been derived for the gain coefficient in a flowing  $\text{N}_2\text{-CO}_2$  system. The validity of this expression rests on two principal assumptions: (1) instantaneous pumping equilibrium is maintained throughout the optical cavity and (2) the beam intensity changes slowly over the characteristic distance for lower level decay. Although these conditions are not always satisfied in practice, particularly near the upstream edge of the beam, it is believed that even in these instances equation (191) provides a qualitatively accurate description of gain saturation in a GDL. The gain coefficient defined by equation (191) is then included in the complex transmission function

$$t = \exp \left[ g(x,y;I) \Delta L/2 + i\Delta\phi(x,y;I) \right] \quad (193)$$

to describe the effect of the medium gain throughout a segment of length  $\Delta L$ . Here,  $\Delta\phi$  represents a phase shift due to possible refractive index variations.

### 30. SUBROUTINE SLIVER

a. Purpose -- Subroutine SLIVER, shown in Figure 64, applies an annular aperture to the field. It can be centered anywhere in the mesh.

b. Relevant formalism -- The field is set to zero interior to the annular aperture. Mesh squares intersecting the aperture edge have the field linearly adjusted for the relative area intersected by the aperture edge.

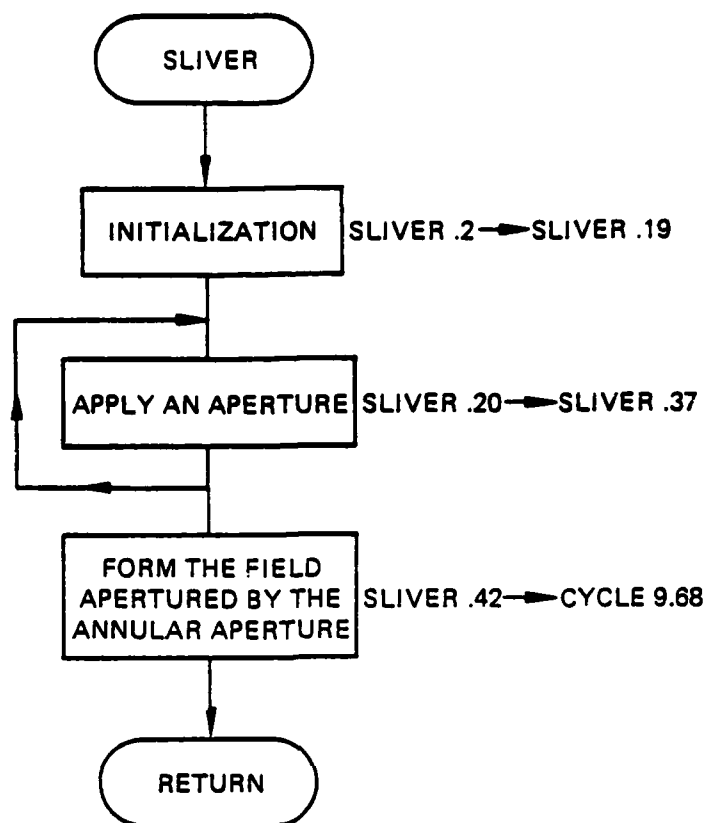

Figure 64. Subroutine SLIVER organization.

c. Fortran

Arguments

RIN = Radius of the OUTER edge of the annulus (cm)

ROUT = Radius of the INNER edge of the annulus (cm)

NOTE: Both RIN and ROUT must be negative to call "SLIVER" since if DOUT ( $=2 \times \text{RIN}$ ) and DIN ( $=2 \times \text{ROUT}$ ) are negative in the GDL call IFLOW = 4 section SLIVER is called instead of APRTR.

Common Variables Altered

CFIL = CFIL contains the original field

CU = CU is used to find the aperture field.

The Logic of Subroutine SLIVER is the following:

The final field is formed by subtracting an apertured field from the original. The aperture has a center disk of radius ROUT while the inner radius of the outer edge is RIN.

The center obscuration is first removed (IIN=0), then the outer obscuration (IIN=1). This apertured field (CU) is then subtracted from the original field (stored in CFIL) to form the field apertured by the annular aperture (CU).

The SLIVER subroutine computer printout follows.

### 31. SUBROUTINE SPIDER

a. Purpose -- The SPIDER subroutine shown in Figure 65 applies an obscuration to the complex amplitude field in the form of several support struts, such as those used in a Cassegrain telescope system. Up to six struts at separate angles may be modeled. The result of the obscuration is listed in the output stream as an aperture loss.

b. Relevant formalism -- An angular deviation limit  $\alpha$  calculated from the obscuration inside diameter  $d$ , the grid spacing  $\Delta x$ , and the strut width  $w$ , according to

$$\alpha = \sin^{-1} (w+2\Delta x)/d \quad (194)$$

Field points whose inclination angle is not within  $\pm\alpha$  of a strut angle are assumed to be unobscured. Those points falling within this limit are subjected to closer inspection.

The distance  $\delta$  from a grid center  $(x,y)$  to the strut centerline is calculated by

$$\delta = |y \cos\theta - x \sin\theta| \quad (195)$$

where  $\theta$  is the strut angle. The half-width of a grid measured along a normal to the strut  $h$  is calculated by

$$h = x/2./A'MAX (|\sin\theta|, |\cos\theta|) \quad (196)$$

then the maximum and minimum distance of the grid area from the centerline,  $d_{\max}$  and  $d_{\min}$  are

$$\begin{aligned} d_{\max} &= \delta + h \\ d_{\min} &= \delta - h \end{aligned}$$

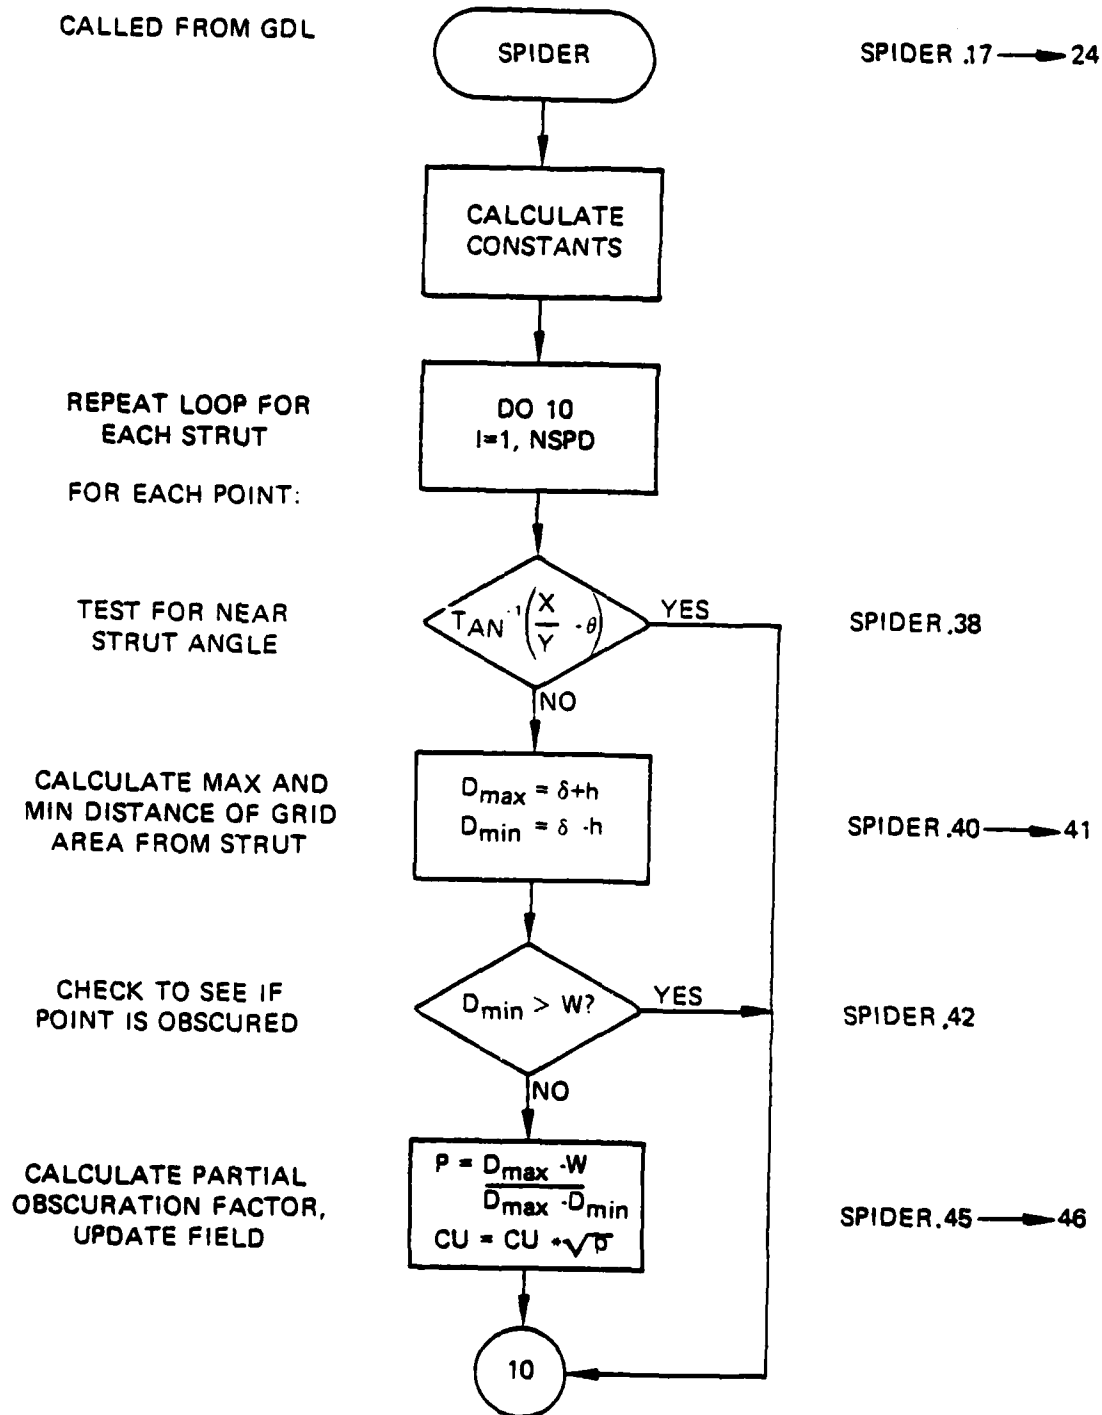

Figure 65. Subroutine SPIDER flow chart.

Points where  $d_{\min}$  is greater than the strut half width  $h_s$  are not obscured.  
 Points where  $d_{\max}$  is less than the strut half width are totally obscured.  
 The intensity of all other points is weighted according to

$$\text{intensity weighting} = (d_{\max} - h_s) / (d_{\max} - d_{\min}) \quad (197)$$

### 33. SUBROUTINE STEP

a. Purpose -- Subroutine STEP shown in Figure 67 is used to propagate the field through a vacuum. It also calculates Strehl intensity.

b. Relevant formalism

(1) Propagation -- STEP allows for two types of propagation

(a) Constant area mesh -- This type is used to propagate collimated and quasi-collimated beams. It assumes that edge spreading of the beam due to diffraction is not severe enough for the beam to get too close to the edge of the calculation region.

(b) Variable area mesh (VAMP) -- VAMP is used to propagate beams containing phase with curvature. As will be shown, the curvature is first removed from the field. The (collimated) field is then propagated an equivalent propagation distance which is defined by the formalism. After propagation, the propagated curvature is returned to the field.

The theory of VAMP propagation is developed in Section 5-D of AWFL-TR-73-231 and is repeated here for continuity.

First, consider constant area mesh propagation. The scalar wave function propagating in the Z-direction is written

$$\psi(\vec{r}, t) = U(\vec{r}) e^{i(\omega t - kz)} \quad (198)$$

The function  $\psi(x, t)$  obeys the scalar wave equation derived from Maxwell's equations

$$\nabla^2 \psi = \frac{1}{c^2} \frac{\partial^2 \psi}{\partial t^2} \quad (199)$$

If one assumes that

$$\frac{\partial^2 \psi}{\partial t^2} \ll k \frac{\partial u}{\partial z} \quad (200)$$

then  $u(x)$  obeys the paraxial wave equation

$$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} - 2ik \frac{\partial u}{\partial z} = 0 \quad (201)$$

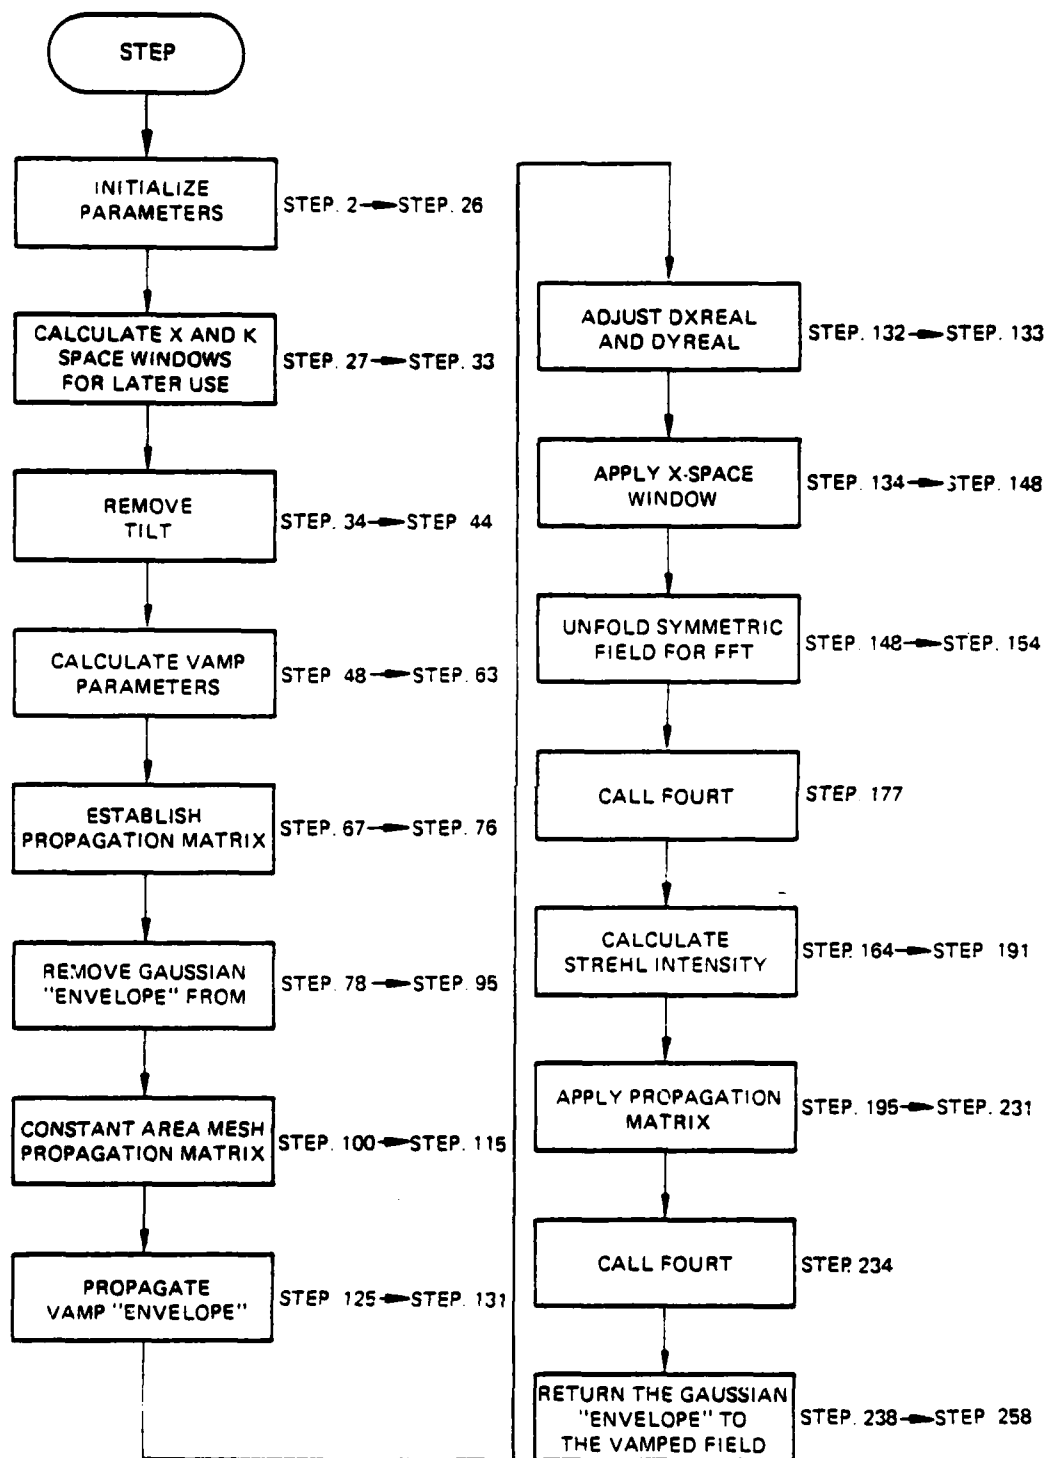

Figure 67. Subroutine STEP organization.

By using the method of Fourier Transforms  $u(x)$  is

$$u(\vec{r}) = \iint_{-\infty}^{\infty} df_x df_y e^{2\pi i(f_x x + f_y y)} U(f_x, f_y) e^{i\pi \lambda Z (f_x^2 + f_y^2)} \quad (202)$$

where

$$U(f_x, f_y) = \iint_{-\infty}^{\infty} dx' dy' e^{-2\pi i(f_x x' + f_y y')} U(x', y', 0)$$

The Fourier Transforms are efficiently performed by using the FFT.

For variable area mesh, the following approach is used:

The spreading of the beam is estimated by that of a Gaussian reference beam with the same radius of curvature as the physical beam. This curvature is removed so that during propagation the beam continues to fill the calculation region.

Propagation of a Gaussian beam is easily handled by assuming knowledge of the associated Gaussian plane wave. According to Siegman, Chapter 8, (Ref. 14), a Gaussian plane wave (at  $Z = 0$ )

$$U_0(x_0, y_0) = \sqrt{\frac{2}{\pi}} \left( \frac{1}{w_0} \right) e^{-(x_0^2 + y_0^2)/w_0^2} \quad (203)$$

when propagated a distance  $Z$  becomes

$$u(x, y, z) = \sqrt{\frac{2}{\pi}} \left( \frac{1}{w(z)} \right) e^{-i(kz - \psi(z))} e^{-(x^2 + y^2) \left( \frac{k}{2R(z)} + \frac{1}{w(z)^2} \right)} \quad (204)$$

where

$$R(z) = z + \frac{z_R^2}{z} \quad \psi(z) = \tan^{-1} \left( \frac{z}{z_R} \right)$$

$$w(z) = w_0 \sqrt{1 + \left( \frac{z}{z_R} \right)^2}$$

14. Siegman, A. E., An Introduction to Lasers and Masers, McGraw-Hill, New York, 1971.

with

$$z_R = \frac{\pi w_0^2}{\lambda}, \text{ the Rayleigh range.}$$

Therefore, to propagate a Gaussian beam of waist  $w(Z)$  and radius of curvature  $R(Z)$  a distance  $\Delta Z$ , the following approach should be taken:

Knowing the waist and radius of curvature, one can determine the spot size  $w_0$  and distance to the spot size  $Z$ , according to

$$z_1 = \frac{R(z_1)}{1 + \left( \frac{\lambda R(z_1)}{\pi w(z_1)} \right)^2} \quad (205)$$

$$w_0 = \frac{w(z_1)}{\sqrt{1 + \left( \frac{\pi w(z_1)}{\lambda R(z_1)} \right)^2}} \quad (206)$$

Then, from this origin a distance  $Z_2 = Z_1 + \Delta Z$  is propagated to determine the desired wave function.

Since it is known how a Gaussian wave propagates, it is possible that transforming a given wave with a spherical wave front to Gaussian coordinates could result in the propagation of a quasi-collimated wave. The appropriate transformation is found to be

$$U(\mathbf{r}) = \frac{V(\mathbf{r})}{w(z)} e^{i \left[ \frac{k(x^2 + y^2)}{2R(z)} + \tan^{-1} \left( \frac{z}{z_R} \right) \right]} \quad (207)$$

where  $Z$  is the distance from the current reference Gaussian beam, defined by  $R(Z)$  and  $w(Z)$  to its spot.  $z_R$  is the Rayleigh range of this reference Gaussian beam.

By transforming to Gaussian coordinates:

$$X = x/w(z) \quad Z = \tan^{-1} \left( \frac{z}{z_R} \right) \quad Y = y/w(z) \quad (208)$$

The beam transformation is written as

$$u(\vec{X}) = v(\vec{X}) \frac{\cos z}{w_0} e^{-i(X^2+Y^2) \tan z + iz} \quad (209)$$

Inserting this equation into the paraxial wave equation results in the following differential equation in terms of Gaussian coordinates

$$-4i \frac{\partial v}{\partial z} + \frac{\partial^2 v}{\partial X^2} + \frac{\partial^2 v}{\partial Y^2} + 4(1-(X^2+Y^2)) v = 0 \quad (210)$$

which, except for the quadratic, is similar to the paraxial wave equation. The quadratic term  $(X^2 + Y^2)v$  can be dropped if the reference Gaussian parameters and propagation distance are chosen so that  $v$  is equal to zero whenever  $X$  or  $Y$  approaches 1. This implies that the initial waist of the reference Gaussian be much larger than the size of the beam to be propagated. The propagation distance  $\Delta Z$  must then be restricted so that the waist of the reference beam remains large compared with the beam size throughout the propagation. With these restrictions, the equation for  $v$  in Gaussian coordinates becomes

$$\frac{\partial^2 v}{\partial X^2} + \frac{\partial^2 v}{\partial Y^2} + 4v - 4i \frac{\partial v}{\partial z} = 0 \quad (211)$$

As is the collimated case, Fourier Transform analysis gives the following result:

$$v(X,Y,Z) = \iint_{-\infty}^{\infty} df_x df_y V(f_x, f_y, Z) e^{2\pi i(f_x X - f_y Y)} \quad (212)$$

where

$$V(f_x, f_y, Z) = V(f_x, f_y, Z_1) e^{-i \left[ 1 - \pi^2 (f_x^2 + f_y^2) \right] (Z - Z_1)}$$

and

$$V(f_x, f_y, z_1) = \iint_{-\infty}^{\infty} dX dY V(X, Y, Z) e^{-2\pi i (f_x X + f_y Y)}$$

the propagated wavefunction is then  $v(X, Y, Z)$  multiplied by the propagation envelope:

$$u(x, y, z) = V(X, Y, Z) \frac{\cos Z}{w_0} e^{i(X^2 + Y^2) \tan Z + iZ} \quad (213)$$

where

$$X = \frac{x}{w(z)} \quad Y = \frac{y}{w(z)} \quad z_1 = \tan^{-1} \left( \frac{z}{z_R} \right)$$

$z$  being the final distance from the reference spot. If the propagation takes place well outside of the Rayleigh range,  $Z$  is much greater than  $Z_R$  and the expansion of the arctangent for large argument can be used:

$$\begin{aligned} Z - Z_1 &= \tan^{-1} \left( \frac{z}{z_R} \right) - \tan^{-1} \left( \frac{z_1}{z_R} \right) \\ &= \left( \frac{\pi}{2} - \frac{z_R}{z} \right) - \left( \frac{\pi}{2} - \frac{z_R}{z_1} \right) \\ &= z_R \left( \frac{1}{z_1} - \frac{1}{z} \right) \end{aligned} \quad (214)$$

(2) Strehl intensity -- Since subroutine STEP propagates the beam using Fourier Transforms, the Strehl intensity is easily calculated.

The Strehl intensity gives an irradiation of the amount of aberration present in the beam at a given limiting aperture. It is defined as follows: Consider a field  $U(x, y)$ . The field in the Fraunhofer diffraction region (the far field) is given by equations (4) through (13) in Goodman:

$$\vec{u}(\vec{x}) = e^{ikz} e^{i\frac{k}{2z}(x^2 + y^2)} \iint_{-\infty}^{\infty} u(\vec{x}') e^{\frac{2\pi i}{\lambda z} (\vec{x} \cdot \vec{x}')} d\vec{x}' \quad (215)$$

Aside from the phase factor in front, this is just the Fourier Transform of the apertured field evaluated at

$$\vec{f} = \frac{\vec{x}}{\lambda z} \quad (216)$$

The Strehl intensity is defined as the ratio of the centerline intensity of the far field to that of a plane wave propagated the same distance coming from the same aperture with the same power. Analytically this is given as

$$I_{\text{STREHL}} = \frac{I_{\text{CL-FF}}}{I_{\text{LL-PW-FF}}} = \frac{\left| F(u(\vec{x}')) \right|_{\vec{f}=0}^2}{\left| F(u_{\text{pw}}(\vec{x}')) \right|_{\vec{f}=0}^2} \quad (217)$$

The plane wave centerline intensity is evaluated from

$$\begin{aligned} F(u_{\text{pw}}(\vec{x}')) &= A_0 \int_0^a r dr \int_0^{2\pi} d\theta e^{2\pi i f_r \cos\theta} \Big|_{\vec{f}=0} \\ &= \pi a^2 A_0 \end{aligned} \quad (218)$$

$A_0$  being the plane wave amplitude and  $a$  the radius of the aperture. Assuming a calculation region size of the  $L \times L$  with  $N \times N$  = total number of points, the centerline intensity of the far field for the real beam is found from

$$\begin{aligned} F(u(\vec{x}')) &= \iint_{-\infty}^{\infty} d\vec{x} u(\vec{x}) e^{2\pi i \vec{f} \cdot \vec{x}} \\ &= \int_0^L dx \int_0^L dy u(x, y) e^{2\pi i \vec{f} \cdot \vec{x}} \\ &\approx \sum_{I=1}^N \left(\frac{L}{N}\right) \sum_{J=1}^N \left(\frac{L}{N}\right) U(I, J) e^{2\pi i \left(\frac{L}{N}\right) (If_x + Jf_y)} \end{aligned} \quad (219)$$

where

$$\Delta x = \Delta y = \frac{L}{N} \quad \text{and} \quad x = I \left( \frac{L}{N} \right) \quad y = J \left( \frac{L}{N} \right)$$

assume

$$f_x = \frac{KB}{N} \quad \text{and} \quad f_y = \frac{MB}{N}$$

where B is twice the maximum frequency of the spectrum of u,

then

$$F(u(\vec{x}')) \approx F(K,M) = \left( \frac{L}{N} \right)^2 \sum_{I=1}^N \sum_{J=1}^N U(I,J) e^{2\pi i \left( \frac{LB}{N} \right) \left( \frac{KI}{N} + \frac{MJ}{N} \right)} \quad (220)$$

But from the theory of discrete Fourier Transforms  $LB = N$ , so

$$F(K,M) = \left( \frac{L}{N} \right)^2 \sum_{I=1}^N \sum_{J=1}^N U(I,J) e^{2\pi i (KI + MJ)/N} \quad (221)$$

The whole sum is just the (K,M) output of the FFT routine, so

$$F(K,M) = \left( \frac{L}{N} \right)^2 F_{\text{FFT}}(K, M) \quad (222)$$

The FFT returns the DC value (centerline) at  $F_{\text{FFT}}(1,1)$  so the Strehl intensity is defined as

$$I_{\text{STREHL}} = \frac{\left( \frac{L}{N} \right)^4 |F_{\text{FFT}}(1,1)|^2}{(\pi a^2)^2 I_0} \quad (223)$$

where  $I_0 = A_0^2$  = plane wave intensity.

Note: If the beam is not limited by an exit aperture just before the Strehl calculations, it is possible to have  $I_{\text{STREHL}}$  greater than one.

Argument List

DELZ = Distance to be  
RADCY = radius of curvature or the phase front  
WINDOX = x-space cosine data window for FFT  
WINDOK = K-space cosine data window for FFT  
IFG = Vamp control parameter  
      = 1 constant mesh  
      = 2 variable mesh  
ITR = Vamp control parameter  
      = 0 stay in vamp  
      = 1 transform back to constant mesh space  
IPS = Tilt and defocus removal flag  
      = 0 no correction  
      = 1 remove tilt  
      = 2 find defocus radius of curvature  
      = 3 1 + 2 together  
AX }  
AY } = total beam tilt keep track of for beam placement in the  
      inertial coordinate system instead of the beam coordinate  
      system  
NWRT #0 Propagates a wave distance DELZ without altering the stored  
      value of total Z. NWRT = 1. Suppresses Strehl intensity cal-  
      culation as well. NWRT = 1 when STEP is called from QUAL.  
IFLAG #0 Assumes VAMP and/or CAMP parameters are established. It  
      tells the routine to continue the propagation based on  
      previous calculations of waist and curvature.

Common Variables Altered:

CU - becomes the propagated field  
CFIL - is altered if IPS  $\neq$  0 by a call to TILT

X - altered if in VAMP

DXREAL - moved to keep track of center of beam in inertial frame as  
DYREAL the beam propagates

WNOW - VAMP parameter altered to keep track of the current spot size

NREG - Flag to tell whether:

- = 0: Constant area mesh propagation
- = 1: VAMP inside half the Rayleigh range
- = 2: VAMP outside twice the Rayleigh range

Other routines called:

TILT

FOURT

#### 34. SUBROUTINE TBLOOM

a. Purpose -- This subroutine, shown in Figure 68, is used to model four types of thermal blooming which may be seen by a beam as it propagates through an absorptive medium.

The four types are:

1. Transverse
2. Axial
3. Free convective
4. Transient

b. Relevant formalism -- Thermal blooming arises as a consequence of the absorption of laser radiation by the transmitting gas. The absorbed radiation heats the gas and consequently changes its refractive index. These variations in the index of refraction induce phase changes in the propagated beam. Phase changes produced by thermal blooming can result in beam divergence, which overloads apertures and provides a source of high energy feedback. Thermal blooming also degrades beam quality. Thermal blooming models are available in the SOQ library to describe the impact on the beam phase and amplitude produced when thermal blooming occurs in (1) a transverse flow field, (2) an axial flow field, (3) a free convective flow field, and (4) transient conditions with no external flow.

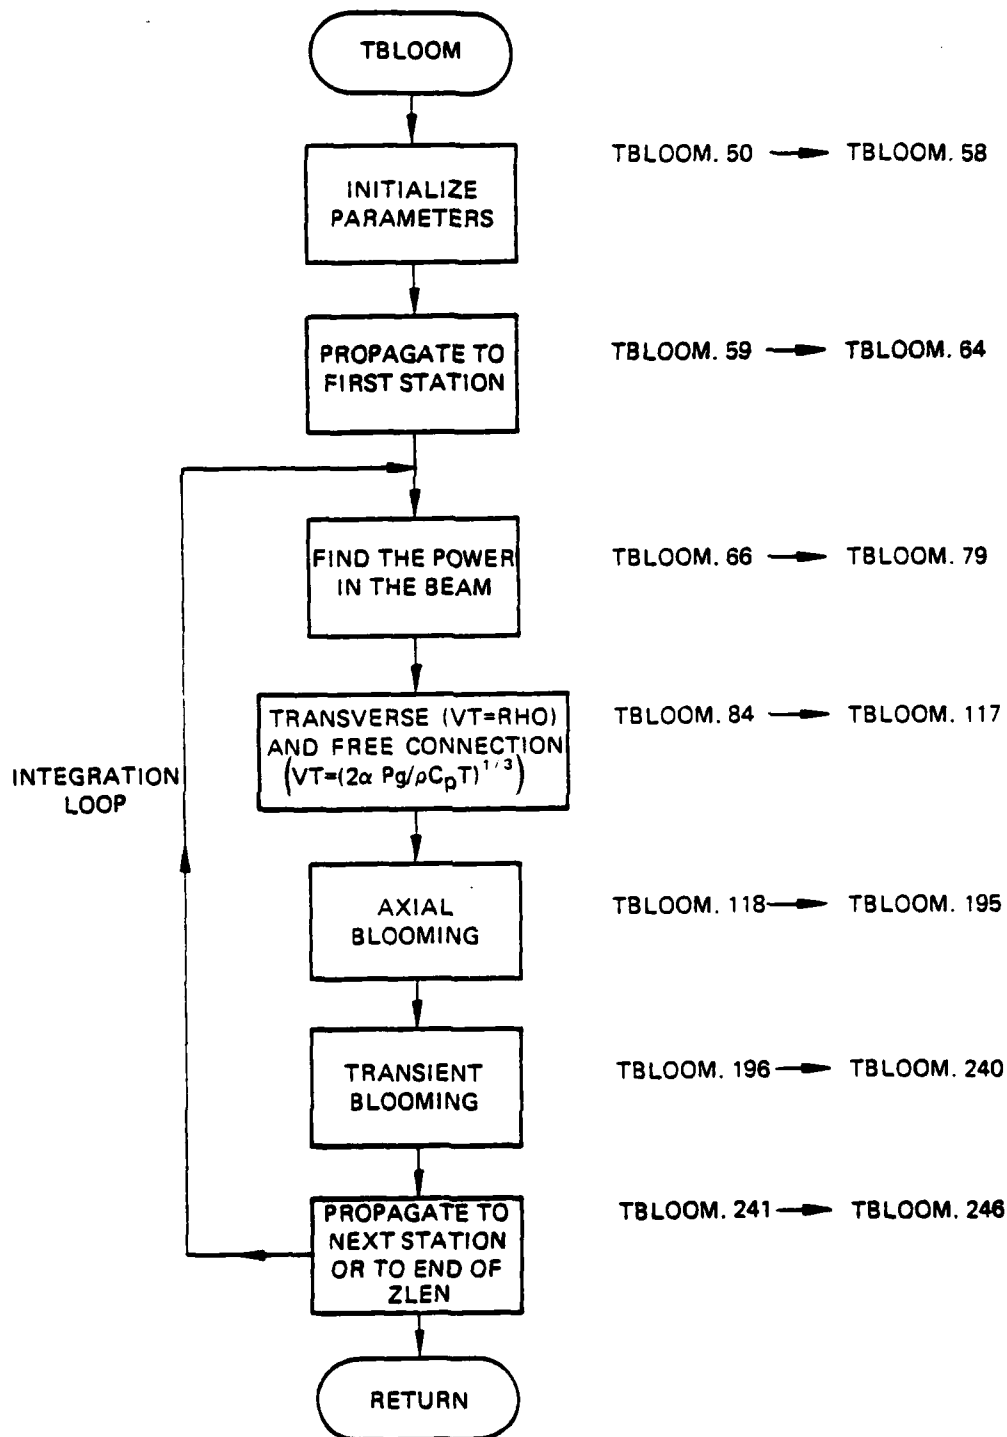

Figure 68. Subroutine TBLOOM flow chart.

Figure 69 schematically demonstrates the procedure used to modify the complex field,  $U(x,y)$ , as it is propagated through a thermal blooming gain phase segment within the SOQ code.

Figure 69. Illustration of thermal blooming model.

As the beam is propagated a distance  $\Delta L$  through the medium, it is continuously interacting with that medium. By requiring that the effect is small, the integrated effect can be approximated by a finite number of discrete steps in the following manner:

Assume each step is of length  $\Delta L$  and that the effect of such a step is approximated by a vacuum propagation to the center ( $\Delta L/2$ ), application of the appropriate transmission function  $t(x,y,l)$ , followed by subsequent vacuum propagation of field the remaining distance ( $\Delta L/2$ ).

The transmission function  $t(x,y,\Delta L, I(x,y))$  can be assumed to be of the form

$$t(x,y,l) = \exp \left[ \frac{\alpha \Delta L}{2} - i \Delta \phi \right] \quad (224)$$

where  $\alpha$  is the absorptivity of the medium and  $\Delta \phi$  can be written

$$\Delta\phi = \frac{2\pi}{\lambda} \frac{dn}{dt} \int_0^{\Delta L} \delta T \, dz' \quad (225)$$

$$\delta T = \delta T(x, y, z)$$

Employing the usual Gladstone-Dale relationship to approximate the index  $n$ , ( $n = 1 + \rho C$ ) and the equation of state for an ideal gas ( $P = \frac{RT}{M}\rho$ ), the expression for  $\Delta\phi$  becomes (assuming constant pressure)

$$\Delta\phi = \frac{2\pi}{\lambda} \left( -\frac{\rho C}{T} \right) \int_0^{\Delta L} dz \, \delta T(x, y, z) \quad (226)$$

$\delta T$  represents the temperature variation across the beam as a result of one of the four types of thermal blooming. It is found in the following manner:

(1) Transverse blooming -- It is assumed that the wind is blowing with speed  $V_T$  (cm/scan) from the negative  $x$ -direction. The resulting temperature variation is:

$$\delta T_T = \frac{\alpha}{\rho C_p V_T} \int_{-\infty}^x I(x', y, z) \, dx' \quad (227)$$

where  $I$  is the intensity of the beam.

(2) Axial blooming -- It is assumed that the wind blows in the same direction the beam is traveling with speed  $V$  (cm/sec) resulting in

$$\delta T_{ax} = \frac{\alpha}{\rho C_p V_{ax}} \int_0^x I(x, y, z) \, dz' \quad (228)$$

(3) Free convection -- The temperature variation due to thermal gradients caused by absorption is:

$$\delta T_c = \frac{\alpha}{\rho C_p V_c} \int_{-\infty}^x I(x', y, z) \, dx' \quad (229)$$

where

$$V_c = \left( \frac{2\alpha P z g}{\rho C_p T} \right)^{\frac{1}{3}}$$

$P(Z')$  being the total power in the beam at  $Z'$  and  $g$ , the acceleration due to gravity.

(4) Transient -- Finally, in the process of establishing free convection, the beam has a residence time  $T_{(sec)}$  during which the temperature variation is

$$\delta T_{tran} = \frac{\alpha \tau}{\rho C_p} + I \quad (230)$$

c. Fortran

#### Argument List

ALFA	- Absorptivity of the medium ( $\text{cm}^{-2}$ )
CP	- Specific heat (J/g-K)
T	- Temperature (K)
RHO	- (1) if $RHO \leq 1$ , it is the density ( $\text{g/cm}^3$ ) used for free convection (2) if $RHO > 1$ , it is the transverse velocity
ZLEN	- Total length of the blooming medium
NSTEPS	- The number of steps required to adequately represent thermal blooming over a distance ZLEN. Phase per step shift usually kept $\leq \frac{\pi}{8}$
INPT	- Flag for intermediate plots
NPROP	- Same as NSTE in cavity
AXIAL	- Axial velocity (cm/sec) and is $> 0$
DT	- Residency time for transient blooming

None of the above parameters is redefined by this subroutine.

#### Commons:

The variables in common which are modified are:

- (1) CU: the effect of the blooming is applied to CU
- (2) CFIL: due to its equivalence with the PH and W arrays, it is modified when they are defined.

Computer printouts of subroutine TBLOOM follow.

### 35. SUBROUTINE THERML

a. Purpose -- Since uncooled mirror glass has such a low coefficient of thermal expansion, the mirror surface heats up as the beam hits it, thus heating up the surrounding boundary layer of air. Subroutine THERML, shown in Figure 70, models the phase change impressed on the beam due to thermal gradients in the boundary layer of air.

b. Relevant formalism -- The theory of this phenomenon was developed by Humphreys and Wick (Ref. 15) of AFWL.

15. Humphreys, W. W. and R. V. Wick, "Change in Optical Path Length Near a Hot Mirror Surface," Laser Digest, AFWL-TR-75-140, 1975, p. 9.

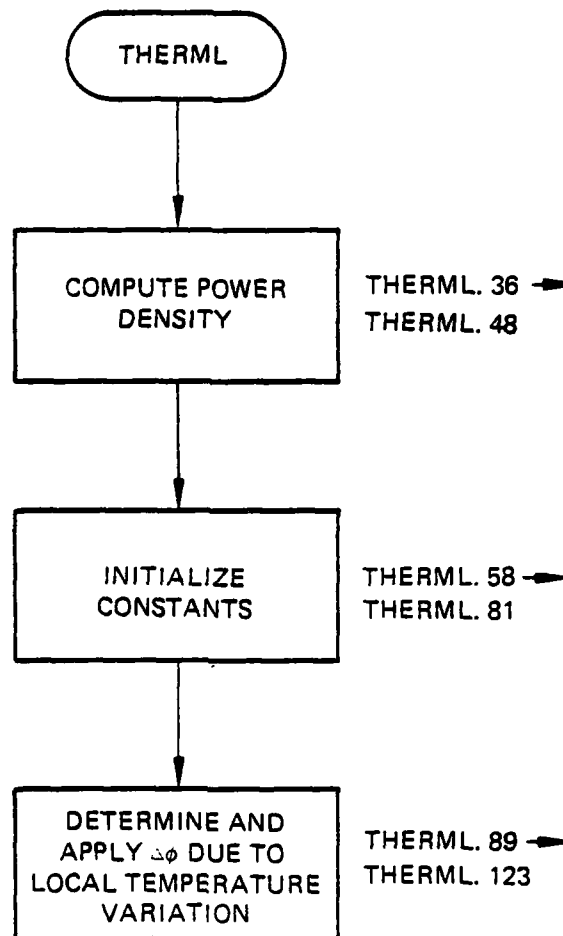

Figure 70. Subroutine THERML organization.

Following Humphreys and Wick, assume that the times of interest are short enough to consider the mirror to be a semi-infinite slab. From the theory of heat conduction the time for heat to traverse a length  $L$  is  $t = L^2/\alpha$ . Thus, for mirrors of thickness  $L$ , the time during which the mirror acts like a semi-infinite slab is  $\ll L^2/\alpha$ . Assume also that for these times one can neglect natural convective cooling. Therefore, the air can also be modeled as a semi-infinite slab. The one-dimensional heat equation is then assumed to apply for both the mirror and the air:

$$\frac{\partial^2 T_m}{\partial x_m^2} = \frac{1}{\alpha_m} \left( \frac{\partial T_m}{\partial t} \right) \quad \frac{\partial^2 T_a}{\partial x_a^2} = \frac{1}{\alpha_a} \left( \frac{\partial T_a}{\partial t} \right) \quad (231)$$

Common variable altered:

CU = the field is modified by the boundary layer  
temperature gradients.

Subroutines called: OUTPUT

where the coordinates are seen in Figure 71.

Figure 71. One-dimension heat diagram of mirror and air.

Initially, both the air and the mirror are at the same temperature  $T_0$

$$T_m(x_m, 0) = T_0 = T_a(x_a, 0) \quad (232)$$

For the times considered, the heat does not have time to diffuse to the back boundary of either the mirror or the air. This boundary condition can be written

$$T_m(\infty, t) = T_0 = T_a(\infty, t) \quad (233)$$

The air and the mirror are assumed to maintain the same temperature at their joint boundary so

$$T_m(0, t) = T_a(0, t) \quad (234)$$

The remaining condition to be applied is that of heat balance at the joint boundary. By Fourier's law

$$-k_m \left. \frac{\partial T_m}{\partial x_m} \right|_{x_m = 0} = \alpha I \quad (235)$$

where  $\alpha$  is the absorptivity of the mirror. Similarly using Fourier's law at the air boundary

$$-k_a \left. \frac{\partial T_a}{\partial x_a} \right|_{x_a = 0} \quad (236)$$

By combining these two equations, the joint heat balance equation at the boundary becomes:

$$-k_m \left. \frac{\partial T_m}{\partial x_m} \right|_{x_m = 0} - k_a \left. \frac{\partial T_a}{\partial x_a} \right|_{x_a = 0} = \alpha I \quad (237)$$

Since both the media obey the same form of equation, consider the solution of the following equation:

$$\frac{\partial^2 T}{\partial x^2} = \frac{1}{\alpha} \frac{\partial T}{\partial t} \quad (238)$$

Finding the Laplace Transform of the above equation gives

$$\frac{d^2 \bar{T}(x,s)}{dx^2} = \frac{1}{\alpha} \left( -T(x,0) + s \bar{T}(x,s) \right) \quad (239)$$

where,

$$\bar{T}(x,s) = \int_0^{\infty} dt e^{-st} T(x,t)$$

Noting that  $T(x,0) = T_0$  for both the mirror and the boundary layer, one can rewrite this as

$$\frac{d^2}{dx^2} \left( \bar{T}(x,s) - \frac{T_0}{s} \right) = \frac{s}{\alpha} \left( \bar{T}(x,s) - \frac{T_0}{s} \right) \quad (240)$$

which integrates to give

$$\bar{T}(x,s) = \frac{T_0}{s} + A(s) \epsilon^{\sqrt{\frac{s}{\alpha}} x} + B(s) \epsilon^{-\sqrt{\frac{s}{\alpha}} x} \quad (241)$$

The boundary condition for  $x \rightarrow \infty$  implies that  $A = 0$  for both media.

Therefore

$$\bar{T}(x,s) - \frac{T_0}{s} = B(s) \epsilon^{-\sqrt{\frac{s}{\alpha}} x} \quad (242)$$

To proceed further, it is necessary to determine  $B(s)$ . This is done using the joint boundary conditions. Recall that

$$-k_m \left. \frac{\partial T_m}{\partial x_m} \right|_{x_m=0} = -k_a \left. \frac{\partial T_a}{\partial x_a} \right|_{x_a=0} = \alpha I$$

Assuming  $(\alpha I)$  to be constant in time, this transforms to

$$-k_m \left. \frac{\partial \bar{T}_m}{\partial x_m} \right|_{x_m=0} = -k_a \left. \frac{\partial \bar{T}_a}{\partial x_a} \right|_{x_a=0} = \frac{\alpha I}{s} \quad (243)$$

but

$$\left. \frac{\partial \bar{T}}{\partial x} (x,s) \right|_{x=0} = -\sqrt{\frac{s}{\alpha}} * B(s) \epsilon^{-\sqrt{\frac{s}{\alpha}} x} \Big|_{x=0} = -\sqrt{\frac{s}{\alpha}} B(s) \quad (244)$$

Therefore

$$-k_m \left( -\sqrt{\frac{s}{\alpha}} B_m \right) - k_a \left( -\sqrt{\frac{s}{\alpha}} B_a \right) = \frac{\alpha I}{s} \quad (245)$$

Recall that at  $x = 0$ ,  $T_m(0,t) = T_a(0,t)$ . This implies that  $B_m(s) = B_a(s)$ .

Therefore

$$B_a = B_m = \frac{\alpha I}{s\sqrt{s}} \frac{I}{\frac{k_m}{\sqrt{\alpha_m}} + \frac{h_a}{\sqrt{\alpha_a}}} \quad (246)$$

The equation for the air to be back-transformed is therefore

$$\bar{T}_a(x_a, s) - \frac{T_o}{s} = \frac{\frac{\alpha I}{\sqrt{\alpha_m}} + \frac{k_a}{\sqrt{\alpha_a}}}{s} \frac{e^{-s \left( \frac{x_a}{\sqrt{\alpha_a}} \right)}}{s} \quad (247)$$

Note that  $\bar{T}_m(x_m, t)$  obeys a similar equation with the  $a$  and the  $m$  subscripts interchanged. Recall the following Laplace Transform theorems:

$$L(T_o) = \frac{T_o}{s}$$

$$\frac{1}{s} L(f(t)) = L \left( \int_0^t dt f(t) \right) \quad (248)$$

and

$$\frac{e^{-a\sqrt{s}}}{\sqrt{s}} = L \left( \frac{e^{-a^2/4t}}{\sqrt{\pi t}} \right) \quad (249)$$

The equation for  $T_a(x_a, t)$  is therefore

$$T_a(x_a, t) - T_0 = \frac{\alpha I}{\frac{km}{\sqrt{\alpha_m}} + \frac{ka}{\sqrt{\alpha_a}}} \int_0^t \frac{e^{-\frac{x_a^2}{4\alpha_a t'}}}{\sqrt{\pi t'}} dt' \quad (250)$$

or

$$\begin{aligned} \Delta T_a(x_a, t) &= T_a(x_a, t) - T_0 \\ &= \frac{\alpha I}{\frac{km}{\sqrt{\alpha_m}} + \frac{ka}{\sqrt{\alpha_a}}} e^{-\frac{x_a^2}{4\alpha_a t}} \left\{ -\frac{x_a}{\sqrt{\alpha_a}} \operatorname{erfc}\left(\frac{x_a}{2\sqrt{\alpha_a t}}\right) \right\} \end{aligned} \quad (251)$$

The phase change in the beam induced by this variation in temperature is given by

$$\Delta \phi(x, y, I) = 2 \left( \frac{2\pi}{\lambda} \right) \int_0^{4\sqrt{\alpha_a t}} \left( \frac{dn}{dT_a} \right) \Delta T_a(dx_a) \quad (252)$$

The factor of 2 is due to the fact that the beam passes through the boundary layer twice. The limit on the integral is seen to be the practical point at which the variation in temperature becomes negligible. This limit is important to estimate since the integral is to be done numerically.

As in TBLOOM,  $dn/dt$  is found by the Gladstone-Dale law

$$N = 1 + \rho C \quad (253)$$

and the equation of state of a perfect gas

$$\rho = \frac{MP}{RT} \quad (254)$$

at constant pressure

$$\frac{dn}{dt} = \frac{-\rho C}{T} \quad (255)$$

It is assumed that the effect is small enough that the integral may be approximated by a finite number of steps. Four steps are chosen here.

c. Fortran

### 36. SUBROUTINE TILT

a. Purpose -- Subroutine TILT, shown in Figure 72, can be used to remove beam tilt and will calculate the radius of curvature of a beam.

b. Relevant formalism -- To remove small amounts of beam tilt, the following formalism is used. Large fixed tilts, such as result from mirrors set at an angle to the beam axis, are removed by the system analyst in defining the equivalent collimated system.

Consider an input field  $U(x,y)$  incident on an optical element with transmission function  $t(x,y)$  yielding an output  $U'(x,y)$ .

$$\begin{aligned}
 U'(x,y) &= t(x,y) U(x,y) \\
 &= A \exp(i\phi)
 \end{aligned}
 \tag{256}$$

Figure 72. Subroutine TILT organization.

For removal of beam tilt from a field  $U(x,y)$  the transmission function must be of the form

$$t_{\text{TILT}}(x,y) = e^{-i(a_x x + a_y y)} = e^{-i\vec{a} \cdot \vec{x}} \quad (257)$$

where  $a_x = h\theta_x$  and  $a_y = h\theta_y$  define the tilt angles to be removed.

Similarly, the phase curvature is removed by the following transmission function

$$t_{\text{SPHERE}}(x,y) = e^{-i \frac{k}{2R} (x^2 + y^2)} \quad (258)$$

To calculate the constants  $a_x$  and  $a_y$  for an arbitrary field distribution,  $U(x,y)$ , define the following functional to be minimized:

$$F_{\text{TILT}} = \iint dx dy |U(x,y)|^2 \left[ \nabla(\phi - a_x x - a_y y) \right]^2 \quad (259)$$

or

$$F_{\text{TILT}} = \iint dx dy |U(x,y)|^2 \left[ \left( \frac{\partial \phi}{\partial x} - a_x \right)^2 + \left( \frac{\partial \phi}{\partial y} - a_y \right)^2 \right]$$

the resulting expression for  $\vec{a}$  is

$$\vec{a} = \langle \vec{\nabla} \phi \rangle \quad (260)$$

where,

$$\langle \vec{\nabla} \phi \rangle = \frac{\iint dx |U(\vec{x})|^2 \vec{\nabla} \phi}{\iint dx |U(\vec{x})|^2} \quad (261)$$

$\nabla \phi$  is easily found from the field data by noting that

$$\text{Im}(U^* \vec{\nabla} U) = |U|^2 \vec{\nabla} \phi \quad (262)$$

Once the tilt is removed, a similar procedure to remove phase curvature is used. Recall that the transmission function  $t_{\text{SPHERE}}(x,y)$  needed is of the form

$$t_{\text{SPHERE}}(x,y) = e^{-ik\left(\frac{x^2+y^2}{2R}\right)} \quad (263)$$

The new functional to be minimized is

$$F_{\text{SPHERE}} = \iint dx dy \left| U(x,y) \right|^2 \left[ \nabla \left( \phi - b \left( \frac{x^2 + y^2}{2} \right) \right) \right]^2 \quad (264)$$

which results in

$$b = \frac{\langle \vec{x} \cdot \vec{\nabla} \phi \rangle}{\langle \vec{x} \cdot \vec{x} \rangle} \quad (265)$$

Values of tilt  $a$  and sphere  $b$  are found by an iterative procedure until the values established for these parameters do not change appreciably.

c. Fortran

Argument List

$\left. \begin{array}{l} \text{AX} \\ \text{AY} \end{array} \right\}$  = Total  $x$  and  $y$  tilt in the beam. The amount of tilt removed from the beam by this routine is added to these parameters so that no tilt information is lost.

RADCUR = the negative of the radius of curvature of the beam found by this routine. To produce a "flat" beam the following calculation would be performed.

$$CU^*(I,J) = CU(I,J) * \exp i(\pi/\lambda R) (x^2 + y^2) \quad (266)$$

with  $R$  representing RADCUR

$X = X(I)$  and  $Y = X(J)$

IPS = the parameter that indicates which options in this routine are to be used. IPS is the same parameter as IIPS in name list PROPGT in subroutine GDL. The options are:

IPS = 0 Tilt is not called for  
 = 1 Tilt only is removed  
 = 2 Sphere only found  
 = 3 Both tilt and sphere found,  
 tilt being removed.

#### Common Variables Altered

CU - has tilt removed

CFIL - starts off set to CU, then has both tilt and sphere removed.

Subroutine TILT computer printouts follow.

### 37. SUBROUTINE ERF

a. Purpose -- The function ERF generates the error function

$$\text{erf}(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt \quad (267)$$

or its complement,  $1-\text{erf}(x)$ , for any input value of  $x$ . This subroutine is a copy of the ERF function available from the AFWL scientific program library. Figure 73 shows the Subroutine ERF flow chart.

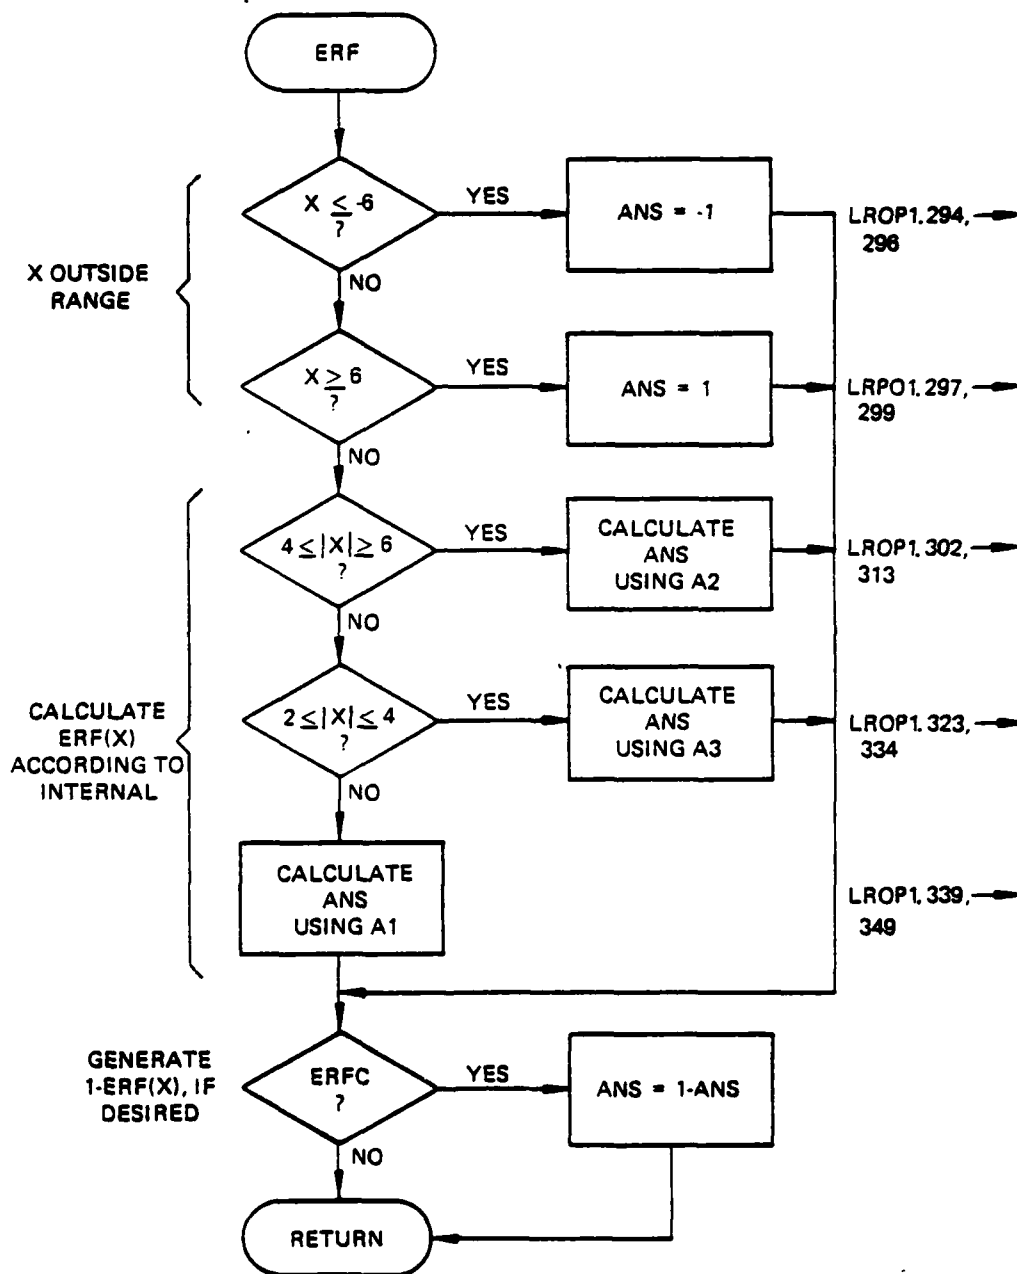

Figure 73. Subroutine ERF flow chart.

b. Relevant formalism -- The error function integral is approximated over discrete intervals of the argument, x, by Tchebichef (Chebychev) polynomials. These polynomials are evaluated in a loop which combines the recurrence relations for generating the polynomials and a running summation of the terms as they are generated. Coefficients for the polynomials are provided in a data statement for three discrete ranges of the argument. Argument values outside this range will return a zero (0).

#### Argument List

ANS	error function value returned to calling program
KODE	flag to indicate computation of erf(x) or 1-erf(x)
XX	error function argument

#### Relevant Variables

A1	array of coefficients used in the polynomial expansion over the range $ xx  \leq 2$ .
A2	coefficient array for the range $4. \leq  xx  \leq 6$ .
A3	coefficient array for the range $2. <  xx  < 4$ .

# SECTION IV

## USER FAMILIARIZATION PACKAGE

The following section contains sample input to run the SOQ code and to logically define the sequence of input to model a sample resonator or optical train the following examples are included:

1. Propagate for Users Guide - Camp
2. Propagate for Users Guide - Vamp
3. Quality for Users Guide
4. Design of a Bare Confocal Resonator
5. Resonator for Users Guide - Bare
6. Resonator for Users Guide - Loaded
7. Sample Code Update

### 1. PROPAGATE FOR USERS GUIDE - CAMP

### 4. DESIGN A BARE CONFOCAL RESONATOR

Assume that one wishes to design a positive branch, unstable bare resonator with a collimated output beam for a given geometric coupling  $C_g$ , length  $L$ , and concave mirror size ( $a_1$ ). To solve this problem design a confocal resonator in the following fashion:

Geometric Resonator Design (Fig. 74).

Define the following parameters

Figure 74. Geometric resonator design.

Recall the definition of geometric coupling.

$$C_g = \frac{A_{OUT}}{A_{TOTAL}} = \frac{\pi a_2^2 - \pi a_1^2}{\pi a_2^2} = 1 - \frac{1}{\left(\frac{a_2}{a_1}\right)^2} \quad (268)$$

But  $M = a_2/a_1$  is the magnification of the resonator, thus

$$C_g = C_g = 1 - \frac{1}{M^2} \quad (269)$$

Or inverting this expression, one finds

$$M = \frac{1}{\sqrt{1 - C_g}} \quad (270)$$

Given the magnification and length of the resonator, one can find the required mirror radii of curvature, since for an aligned confocal resonator both the convex and concave mirror foci are coincident. Figure 75 describes this coincident feature.

Figure 75. Required mirror radii of curvature.

a. The focal lengths can be related to the magnification by noting that

$$\tan \theta = \frac{a_1}{f_1} = \frac{a_2}{f_2} = \frac{a_3}{f_3} \quad (271)$$

therefore

$$M = \frac{a_2}{a_1} = \frac{f_2}{f_1} = \frac{f_1 + L}{f_1} \quad (272)$$

The focal lengths are then found to be

$$f_1 = \frac{L}{M-1} \quad \text{and} \quad f_2 = Mf_1 = \frac{ML}{M-1} \quad (273)$$

Since the radius of curvature of a mirror is twice its focal length, the two radii of curvature are

$$R_1 = \frac{-2L}{M-1} \quad R_2 = -MR_1 = \frac{2ML}{M-1} \quad (274)$$

where the negative sign indicates a convex mirror and the positive, a concave. For example, if  $L = 200$  cm and  $C_g = 0.75$ , the magnification and radii are found to be

$$M = \frac{1}{\sqrt{0.25}} = 2 \quad (275)$$

$$R_1 = \frac{-(2)(200)}{(1)} = -400 \text{ cm} \quad \text{and} \quad R_2 = -(2)(-400) = 800 \text{ cm} \quad (276)$$

b. Tube Fresnel number -- The tube Fresnel number for this resonator can be found by the fact that the expanding pass propagation distance  $L$  has an equivalent collimated propagation length of  $ML$  so the round trip collimated propagation distance is  $(M + 1)L$ . The tube Fresnel number is then (assuming the CVM is 2.0 cm in radius and the beam has a wave length of 10.6  $\mu\text{m}$ ).

$$N_T = \frac{a_1}{(M+1)L\lambda} = \frac{(2)^2}{(5)(200)(10.6 \times 10^{-4})} = 6.29 \quad (277)$$

c. Computer requirements

(1) Overlap -- Since the beam diffracts during propagation, it is necessary to have a large enough calculation region to always contain the beam. The required overlap can be calculated according to Sziklas and Siegman (Ref. 2) as

$$G \geq 1 + \frac{1}{2\pi^2 N_T \epsilon} \quad (278)$$

where  $\epsilon$  is the tolerance on fractional energy loss during propagation. Taking this to be 0.02, one finds the guardband to be

$$G \geq 1 + \frac{1}{2\pi^2 (6.29)(0.02)} = 1.4 \quad (279)$$

Thus the initial calculation region must be at least G times the beam size:

$$DCALC = 1.4 \times 2 \times 2 = 5.6 \text{ cm} \quad (280)$$

(2) Number of points required -- Sziklas and Siegman also show that in order to adequately sample the beam, the number of points in each dimension must obey the following inequality:

$$N_p \geq 4G(G+1)N_T \quad (281)$$

This becomes

$$N_p \geq 4(1.4)(2.4)(6.29) = 85 \quad (282)$$

Standard input for the SOQ deck is 128 by 128 so this criterion is satisfied.

d. SOQ input -- As a result of the above discussion, the parameters used for a bare resonator test case could be the following:

NPTS = 128  
 DCAL = 5.6 cm  
 CVM: RADC = -400 cm  
 DIAOUT = 4.0 cm  
 DIAIN = 0.0 cm  
 DELZ = 200.0 cm  
 CCM: RADC = 800.0 cm  
 DIAOUT = 8.0 cm  
 DIAIN = 0.0 cm

To obtain source printouts of the SOQ code, the user must run the CDC update program. The compile file may be used as a source listing or if the user so desires he may run the Fortran compiler on the code to obtain a compiled version or listing along with any desired Fortran compiler options supported under the CDC NOS/BE system. The file output will contain the desired listings. The following job setup is include as a guide:
